### 1 What's new in Version 5.0

- Inclusion of ionization and recombination effects in level population calculation see Sect. 8.6, Sect. 5.1.1.
- Photoexcitation from any user-provided radiation field see Sect. 8.5 and Sect. 9.7
- Non-maxwellian distribution of electron velocities see Sect. 8.3 and Sect. 9.8
- New data for
  - Fe IX, Fe X, Fe XII, Fe XV (EUV)
  - Fe XVII to Fe XXIV (X-rays)
  - n=3 to n=3 transitions for N-like and O-like ions
  - new ions (P XIV, XV; Cl II, X, XI, XII, XVII; K V, XVII, XIX; Ca VII, VIII; Co XX; Zn XXIII)
- The software has been improved and speeded. Fixed various minor bugs.
- A few new useful routines, in particular:

```
which_line
pop_processes
(see the example section).
```

• Added keV option to calculate/plot spectra in energy units.

The changes introduced to speed the calculations were made necessary by the increasingly larger atomic models now available in CHIANTI, that made the running time of the software of the previous version too long.

The software is backward-compatible, i.e. can be used together with previous versions of the database.

# 2 What was new in Version 4.1

- -Added detailed descriptions of the data file contents.
- -Replaced the continuum plot, that was created with the corrupted version of the itoh.dat file.
- -Corrected instructions for installation within Windows.

### 3 What was new in Version 4.0

This document describes the general characteristics of the new Version 4.0 of the CHIANTI package (database and IDL procedures).

A considerable number of new features, both in the database and the software, have been added (see Young et al., 2003). We have tried to keep a distinction between the previous and the new features in this document.

### Users of previous versions, please NOTICE:

- 1. The procedures to install CHIANTI as a stand-alone package have changed in small but important ways.
- 2. New kinds of files (.fblvl and .psplups) are now being distributed and the format of the .splups files has changed.
- 3. The entire previous software has been rewritten. There are a few minor changes in the way the procedures are called.
- 4. New software has been written.
- 5. The CHIANTI routines now use SolarSoft routines.

The main new features described in this guide are

- New CHIANTI distribution and structure see Sect. 7
- Photoexcitation and Stimulated Emission see Sect. 8.4
- New software see Sect. 6.1 and App. A
- New continuum calculations see Sect. 8.7
- Incorporating proton rates into CHIANTI see App. B
- Incorporating 9 point spline fits into CHIANTI see App. C

Backward compatibility has been assured for almost all cases. In practice, previous users of CHIANTI will be able to use the new V.4 software as before, with just minor changes. On the other hand, software versions prior to 4 are not compatible with the v.4 database.

This document replaces the previous CHIANTI guide (Version 1.0).

### 4 Introduction

CHIANTI is a collaborative project involving researchers based at the Naval Research Laboratory (NRL, Washington DC, USA), Rutherford Appleton Laboratory (RAL, UK), the University College London (UCL, UK), the University of Cambridge (UK), the George Mason University (GMU, USA) and the University of Florence (Italy).

### 4.1 What is CHIANTI

The CHIANTI package consists of a critically evaluated set of atomic data (energy levels, wavelengths, radiative transition probabilities and excitation data) for a large number of ions of astrophysical interest. It also includes a number of ancillary data and a suite of Interactive Data Language (IDL) programs to calculate optically thin synthetic spectra and to perform spectral analysis and plasma diagnostics.

Plasma emission codes have long been used to study UV and X-ray spectral lines emitted from solar or stellar atmospheres. A comparison of the theoretical line intensities with the observed intensities allows a determination of the physical parameters for the plasma (cf Mason and Monsignori Fossi, 1994 and Del Zanna, Landini and Mason, 2002).

It is very important, now that high accuracy atomic data are available, to improve and keep up-to-date the plasma codes.

The CHIANTI database has been used extensively by the astrophysical and solar communities to analyse emission line spectra from astrophysical sources.

The CHIANTI package is freely available at one of the CHIANTI homepages:

- RAL, UK: http://www.chianti.rl.ac.uk/
- NRL, USA: http://wwwsolar.nrl.navy.mil/chianti.html
- UCL, UK: http://www.mssl.ucl.ac.uk/www\_solar/chianti/

or at

• SolarSoft, a programming and data analysis environment for the solar physics community. http://www.lmsal.com/solarsoft/

### 4.2 Important caveats and limitations

As with any atomic data package, CHIANTI has been developed to suite some specific applications in astrophysics, and users should read the CHIANTI papers and the documentation to find out the ranges of applicability of the package.

Currently, some of the main assumptions and limitations of the data and programs are:

- Level excitations occur via collisional excitation by electrons and protons, and photoexcitation from black-body or user-defined radiation fields.
- Electrons and protons have Maxwellian distribution functions. Indeed CHIANTI data include Maxwellian-averaged electron and proton collision strengths. However, it is possible to study the effects of particle distributions that are linear combinations of Maxwellians of different temperatures.
- Electrons and protons have the same temperature.
- The plasma ionization is dominated by collisions (i.e. no photo-ionization is included).
- Atomic processes affecting the ionisation state of an element can be separated from those affecting the level balance within an ion.

A correction to the level populations due to ionization and recombination is included, but it is only valid up to densities above which metastable level populations begin to be non-negligible.

- The plasma is in a steady state.
- All lines are optically thin.
- Line emissivities are reliable only in some (extended) temperature and density ranges. The ranges of temperatures at which the original rates were calculated are normally listed in the files.
- The current ion fractions that are provided within CHIANTI have been calculated assuming equilibrium and without taking into account density effects.
- DEM files are provided only as samples of DEM curves for different physical conditions in the solar atmosphere: the intensities they generate may differ from observed values.

### 4.3 How to acknowledge CHIANTI

The continued development of the CHIANTI database is dependent on continued funding which is generally available if we can demonstrate that the CHIANTI database is of use to astrophysical research. If you use CHIANTI, we only ask that you acknowledge it appropriately in any publications:

Write in the text of any publication the reference to the CHIANTI paper associated with the particular VERSION you have used:

- 1.x (Dere et al., 1997; AASS, 125, 149)
- 2.x (Landi et al. 1999; AASS, 135, 339)
- 3.x (Dere et al., 2001; ApJSS, 134, 331)
- 4.x (Young et al., 2002).

• 5.0 - (Landi et al., 2005)

We would appreciate if you also write in the acknowledgements of any publication the following:

CHIANTI is a collaborative project involving NRL (USA), RAL (UK), and the following Universities: College London (UK), of Cambridge (UK), George Mason (USA), and of Florence (Italy).

If a detail work on a particular ion is done, it would be appropriate to also refer to the original publication. References can be found at the end of each data file or on the WWW. CHIANTI data are included into other databases. It would be appropriate to make that clear to the users so they can trace back the results they use to the original calculations. Users should be aware of what is included in the database, of the approximations applied, and of the atomic data used. The CHIANTI results should not be blindly considered valid in all cases. For example, the CHIANTI predicted emissivities should not be used when considering temperatures outside of the validity ranges.

Any contributions and suggestions to CHIANTI are welcomed. We would appreciate a short description of how you employ CHIANTI.

### 4.4 The CHIANTI consortium members

The CHIANTI project was originally set up by Dr. Ken Dere of the Naval Research Laboratory (Washington, USA), Dr. Helen Mason of the Department of Applied Mathematics and Theoretical Physics at the University of Cambridge (UK), and Dr. Brunella Monsignori-Fossi of the Arcetri Astrophysical Observatory (Florence, Italy). Former students of Dr. Monsignori-Fossi (Dr. Enrico Landi) and Dr. Mason (Dr. Peter Young) helped in the creation of the database. The sad and unexpected death of Dr. Monsignori-Fossi in January 1995, led to Prof. Massimo Landini, a close associate of Dr. Monsignori-Fossi, becoming a new CHIANTI representative (University of Florence).

Additional collaborations have involved Dr. Dave Pike of the Rutherford Appleton Laboratory (RAL), who has written CHIANTI routines to run within the environment of the SOHO/CDS software (and within SolarSoft), and with Dr. Gordon Bromage, Dr. Barbara Bromage and her former student Dr. Giulio Del Zanna of the University of Central Lancashire.

Dr. Enrico Landi, now at the Naval Research Laboratory, Dr. Peter Young, now at RAL, and Dr. Giulio Del Zanna, now at UCL, have continued to be active collaborators in the CHIANTI project.

# 4.5 A short history of the package

1. The first version of the CHIANTI database was released in 1996 and is described in Dere et al. (1997).

Young et al. (1998) used the CHIANTI database for a detailed comparison with observed EUV solar spectra to assess the diagnostic accuracy of the two data sets.

- 2. Version 2.0 (Landi et al. 1999) was released in April 1999. This Version adds atomic data for many of the so called minor ions (Na, P, Cl, K, Ti, Cr, Mn, Co, and Zn), not included in the first version. Because the astrophysical abundances of these elements are relatively low, only the strongest lines of these elements are observed. The addition of the minor ions is an important step in our goal to understand astrophysical spectra in detail. In addition, Version 2.0 extends the beryllium-like sequence, updates some of the data in Version 1, and provides an IDL procedure to calculate the continuum.
- 3. Version 3.0 of the CHIANTI database was released in September 2000 (Dere et al., 2001). In this version the database has been extended to wavelengths shorter than 50Å by including atomic data for the hydrogen and helium isoelectronic sequences, inner-shell transitions and satellite lines and several other ions. In addition, some of the ions already present in the database have been updated and extended with new atomic data from published calculations. The inclusion of the satellites has required a significant modification to the manner in which the spectra have been calculated with CHIANTI. Consequently, a new version of the IDL software has been produced.

In November 2000 we have released a whole new CHIANTI package under SolarSoft.

4. Version 4 of the CHIANTI database, released in Sept. 2002 (Young et al., 2002). The major changes are the inclusion of proton excitation data, principally for ground configuration levels which are close in energy, and of photoexcitation.

The fitting procedure for excitation data, both electrons and protons, has been extended to allow 9 point spline fits in addition to the previous 5 point spline fits. This allows higher quality fits to data from close-coupling calculations where resonances can lead to significant structure in the thermally-averaged collision strengths.

With the addition of H I, He I and N I, the first neutral species have been added to CHIANTI.

Many existing ion data-sets have been updated, in particular most ions of the nitrogen and beryllium isoelectronic sequences. Also, new ions have been added, including Ar IV, Fe VI and Ni XXI.

The continuum routines have been re-written, including a new relativistic free-free continuum, a new free-bound, and a new two-photon continuum. New software has been written.

Minor releases of the database and the software normally include fixes and might occur a few times per year.

# 4.6 How to keep updated on CHIANTI developments

- Read the CHIANTI NEWS page on the WWW.
- Read the HISTORY (software) and README (database) files in the distribution. Any news and changes are logged in these files. The first one has the details of all the software changes, while the second one describes the changes to the database. These files can be found directly in the distribution or via links on the WWW pages.

- We maintain an e-mail list, that is used to distribute information about any developments of the CHIANTI database and programs. To get on the CHIANTI e-mailing list, send us an email.
- We also have an e-mail address for questions:

```
chianti_help@halcyon.nrl.navy.mil
```

### 5 The database structure

The atomic data will continue to be updated regularly as new data are calculated or measured in the laboratory.

It is intended that these atomic data can be accessed and transferred into users own analysis programs, for more sophisticated applications.

### 5.1 Directory structure and atomic data file contents

The database has a tree structure, with the top directory designated with the IDL system variable !xuvtop (and named dbase within SolarSoft):

dbase/

In the top directory are the following files:

```
README_CHIANTI with the description of the current version. VERSION with the version number.
```

Then, there is a series of subdirectories, one for each element present in the database. Each element has a subdirectory for each ion.

The filename prefix for each ion follows spectroscopic notation.

For example, for He, we have He I and He II subdirectories:

```
he/
he_1/
he_2/
```

Then, we have a series of ancillary data that are contained in various subdirectories:

ioneq/	contains ionization frac	tion files.
ip/	has ionization potential	s.
ancillary_data/i	nstrument_responses/	with effective areas.

There are five primary ASCII files for each ion subdirectory. For example, for Fe XIV we have:

#### • fe\_14.elvlc

Specifies the energy levels in  $cm^{-1}$  and Rydbergs. It includes both experimental data and theoretical values of the levels energies.

The energy levels are obtained from NIST. Where necessary, these are supplemented by other laboratory and theoretical values.

Each column in the files has:

- 1. Index of the fine structure energy levels. This index applies to all files for this ion.
- 2. Configuration number, a progressive number. This value is not used by the software.
- 3. Designation of the fine structure level, usually using the notation of LS coupling.
- 4. Integer value of 2S+1, S=spin in standard usage
- 5. Integer value of angular momentum L.
- 6. Symbol for L, i.e. S for L=0, P for L=1, D for L=2, etc.
- 7. Total angular momentum J
- 8. Multiplicity or statistical weight: 2J+1 This value is not used by the software.
- 9. observed energy in cm<sup>-1</sup> (if there is no observed value, it is set to zero). This value is used by the software.
- 10. Observed energy in rydbergs This value is not used by the software.
- 11. theoretical energy in cm<sup>-1</sup> (usually this is the energy from the scattering calculation, but not necessarily). This value is used by the software.
- 12. Theoretical energy in rdybergs. This value is not used by the software.
- 13. There might be further columns but these are not read by the software.

Note that the ordering of the levels does not follow any strict rule.

#### • fe\_14.wgfa

Contains the wavelengths, gf and A values of the transitions and the indices initial and final level corresponding to the indices of the levels as given in the fe\_14.elvlc file. Wavelengths calculated from the theoretical energies are of an indeterminate accuracy and their values are presented as negative values of the calculated wavelength. The 'observed' wavelengths in these files are based on the experimental energies and should be the best available.

The radiative data are taken from published literature and where necessary, supplemented by new calculations.

Each column in the files has:

- 1. index of the lower energy level (consistent with the ordering in the .elvlc file)
- 2. index of the upper energy level
- 3. wavelength in Angstroms. If the wavelength does not connect 2 observed energy levels, the wavelength is given as a negative number. Two-photon transitions are given a zero wavelength.
- 4. gf value (weighted oscillator strength)
- 5. A-value
- 6. In some cases additional columns have extra information on the transition. These are not read by the software.

### • fe\_14.splups

contains the point spline fits to electron collision strengths scaled according to the the rules formulated by Burgess and Tully (1992), as described in Dere et al. (1997). All the atomic data in the CHIANTI database have been visually displayed and assessed for accuracy and any sporadic errors which sometimes creep into published results.

Accurate replication of the temperature averaged collision strength over a wide range of temperatures can be accomplished with the data in this file.

Each column in the files has:

- 1. Z (6 = C)
- 2. ion (3 = III)
- 3. index of the lower level (consistent with the ordering in the .elvlc file)
- 4. index of the upper level
- 5. transition type: see Burgess and Tully, 1992, A&A. types 1-4 follow Burgess and Tully for a 5 point spline fit type 5 = dielectronic recombination excitation rate types 6-9 are the same as 1-4 but for 9 point spline fits
- 6. gf-value
- 7. Energy difference between the two levels in Rydbergs
- 8. Value of scaling parameter 'C' (cf. Burgess and Tully, 1992, A&A).
- 9. 5- or 9-point values (spline fits) of the scaled Upsilons.

### • fe\_14.psplups

This is analogous to the fe\_14.splups file, and contains the point spline fits to proton collision strengths.

• fe\_14.fblvl contains data used for the free-bound calculation. Namely, the statistical weights for each nl shell, and the energy levels in cm<sup>-1</sup>.

### 5.1.1 Ionization/recombination

We created two new files that include the  $\alpha_{ion}$  and  $\alpha_{rec}$  rates. The names of these files follow the usual CHIANTI pattern, and have the .CILVL and .RECLVL suffixes, for ionization and recombination respectively.

Data in these files are tabulated as a function of temperature, at all temperatures for which they are provided.

Currently, all the rates for each ion are given at the same temperature. In the future this will be generalised.

#### 5.1.2 Final comments

The basic structure of the files is to put the data at the beginning of the file followed by

The comments must be enclosed at the end of the file between two lines containing a single '-1'

The original sources are documented in each data file, where also additional and detailed comments written by the CHIANTI member that assessed that particular ion can be found. You can have direct access to the references via the WWW pages.

### 5.2 Additional ancillary data

Some additional data files are needed in various calculations. The software allows the selection of these files, from either a 'standard' selection provided within the database, or by using user defined files that are included in the current working directory, provided they have the proper file extension. For example, it is possible to create a user defined 'myfile.dem'. If the file is in the working directory, then the file will automatically be appended to the list of available DEMs from the CHIANTI database. In other cases, it is possible to select the file by using a widget that allows the user to change directory.

Any user-defined file must have the same format as those already provided (also including a 'comment' section at the end of the file)

#### The list of the ions present in the database

A !xuvtop/masterlist/masterlist.ions file keeps the current list of all the ions in the database. This list is used as default by many routines (for example those that calculate line intensities).

In some cases, it is possible to instead use a user-defined list of ions, to speed the calculation, or to directly supply the routines with a list of ions, via the SNGL ION keyword.

#### Elemental abundances

Files with various elemental abundances are provided in the directory !xuvtop/abund/ Element abundances are in the usual dex notation (Log<sub>10</sub> values, relative to H, that has a Log<sub>10</sub> value of 12).

Options are available within the routines to choose different elemental abundances. User-defined abundance files can also be used, and should have a .abund file extension.

Be aware that any element missing in the elemental abundance file will also be missing in any output created by any software that reads the elemental abundance file.

There is a great deal of controversy over the variation of the elemental abundances in the solar and stellar atmospheres. See the reviews of Meyer (1985, 1993), Widing and Feldman (1992), Mason (1992), Raymond et al. (2001). Also, it should be kept in mind that different analyses can lead to very different results. For example, the ionisation balance, the selection of lines, and the spectroscopic method used can each account for a variation of a factor of two or more in the derived element abundances (see Del Zanna et al., 2002 and references therein).

#### **Ionisation Fractions**

Files giving collisional ionization equilibria are provided in the !xuvtop/ioneq directory. User defined ionisation files should have a .ioneq file extension.

Be aware that most CHIANTI software uses the temperatures in these files as a base for the calculations. For example, if DEM(T) values are supplied, they are first interpolated at the temperatures in the ionization fraction, and the calculations are done at those temperatures.

The ionisation fractions have been taken from the tabulated values in the published literature (e.g. Arnaud & Raymond, 1992; Arnaud & Rothenflug, 1985; Mazzotta et al., 1998).

Be aware that any ion missing in a ionisation fraction file will also be missing in any output created by the software.

Also, be aware that any line missing a temperature overlap with the chosen ionisation fraction would have zero emissivity and will not be output by the software.

Be aware that large differences between different tabulations are present, and that large uncertainties are associated with these calculations. It should be noted that the ionisation equilibrium plays a major role not only in the derivation of the DEM, but also in that one of the elemental abundances. In this respect, it is important to be aware of the fact that a number of ions, in particular those of the Li and Na isoelectronic sequence, present anomalous behaviour (see Del Zanna et al., 2002, and references therein).

#### Differential Emission Measure

Files specifying various standard differential emission measures (DEM) distributions for different solar features are provided in the !xuvtop/dem directory. Additional files for stellar atmospheres will also soon be added. Each file contains the  $Log_{10}$  T and  $Log_{10}$  DEM values in two columns, ordered with increasing temperature.

User-defined DEM files should have a .dem file extension and must have the same format and ordering of the files provided.

Be aware that any line missing a temperature overlap between the ion fraction and the chosen DEM distribution would have zero emissivity and will not be

#### output by the software.

The emission measure distribution in the solar atmosphere is a complex issue. Starting with the pioneering work by Pottasch (1964), spectra in the UV wavelength range have been used to determine the distribution of material as a function of temperature, following various methods. More details can be found in Section 9.16.

#### Other files

Other files are in other miscellaneous directories. For example:

!xuvtop+'/ip/chianti.ip' has the ionization potentials for all the ions;

!xuvtop+'/continuum/ contains data used by the routines that calculate the continuum. For example, gffgu.dat contains the free-free gaunt factors of Sutherland (1998).

### 6 The Software structure

A number of Interactive Data Language (IDL) procedures are also provided as part of the CHIANTI package. These include routines to read the various CHIANTI database files, calculate level populations, line intensities, and temperature dependent and density dependent line intensity ratios.

Most of our efforts have gone into developing well-documented user-friendly IDL routines that meet readily apparent needs. We welcome contributions to the software.

CHIANTI has been run mainly on Sun, Dec Unix workstations and on PCs with Linux. CHIANTI also runs (with some small limitations) under Windows NT and in VMS. Please report to us any problems you might find.

All the IDL routines have been documented with extensive headers giving detailed descriptions and examples. Please read them carefully.

The CHIANTI routines can be grouped into three classes:

- Low-level routines, that for example read the files in the database, or perform the level population calculations. These are not described here and should not be used directly byt the users.
- High-level routines, that perform more complex operations and can be called from the command line. These routines usually output arrays or structures, and optionally produce plots, postscript output or ascii files. Most of them have a long list of options, commanded via KEYWORDS. Please read the headers.
- Higher-level widget-type routines. These routines are more user-friendly, and are complementary of the above class. These routines call low-level or high-level routines to perform the calculations.

The CHIANTI routines are organised in a tree structure. The main level contains some high-level procedures and the HISTORY file, where all modifications to the software are logged.

### 6.1 Short description of the CHIANTI software

Now, a description of the various high-level routines that are present within the CHIANTI software tree is given.

Compared to previous releases, significant changes occurred. Please read Sect. ?? for details. A new set of high-level and higher-level routines has been written for Version 4. The major change for V.4, aside from those already mentioned, has been the way to calculate synthetic spectra and handle line intensities (see Fig. 1):

- A new routine,  $ch_synthetic.pro$ , calculates (without any abundance factor) line intensities or G(T), and outputs a **line intensities CHIANTI structure** (see Sect.E.1 for details). This IDL structure can be **saved and later restored** in various ways, for example using  $ch_write_fits_1$  and  $ch_read_fits_2$ .
- ch\_line\_list.pro takes the line intensities CHIANTI structure and creates ascii or latex files with lists of line identifications and intensities.
- make\_chianti\_spec.pro This program creates the CHIANTI SPECTRUM structure (read Sect. E.2 for details), that contains the synthetic spectrum, created by multiplying by the abundance factor the line intensities and adding the continuum (optional).
- Finally, a new multi-purpose widget ch\_ss.pro has been written. It includes all the above features.

Other routines that previously were only available within SolarSoft are also included now. The users therefore now have various different routines to choose from.

We have kept the older high-level routines, so the user can still use them as before (with slight modifications/additions of keywords). We have updated them and re-written as wrapper routines (essentially that call the newly-written routines) as follows:

### 6.2 How to find help

For the first two classes of routines, by simply typing the name of the routine, a description of how to call the routines, with examples, is printed. For example,

```
IDL > temperature_ratios
IDL > temperature_ratios,ion,wmin,wmax,Log10(tempmin),Log10(tempmax),$
IDL > temperature,ratio,description,$
IDL > [pressure= ,density= , psfile= , outfile= ]
IDL >
IDL > i.e.:
IDL > temperature_ratios,'c_5',40.,50.,5.,7.,temp,rat,desc
```

In any case the best way to understand what a routine does and how it works is to **read** the header documentation with e.g.:

Table 1: List of main-level routines

	Table 1: List of main-level routines  Synthotic spectra
ah aa	Synthetic spectra  Multi num accomidate to calculate line intensities, enecte synthetic anectra
ch_ss	Multi-purpose widget to calculate line intensities, create synthetic spectra
	adding the continuum, tables and various outputs.
synthetic	Calculates a synthetic spectrum. Outputs arrays.
synthetic_plot	Plots the spectrum created by synthetic and interactively identify lines
isothermal	Calculates a synthetic spectrum with an isothermal approximation. Outputs arrays.
make_chianti_spec	Creates a synthetic spectrum. Works with structures.
-	Line intensities
ascii_wvl_dem	Creates an ascii file with a list of line identifications and intensities.
latex_wvl_dem	Creates a latex file with a list of line identifications and intensities.
ch_synthetic	Multi-purpose routine that calculates line intensities (without any abun-
•	dance factor), and outputs an IDL structure.
ch_line_list	Multi-purpose routine that creates ascii and latex files with lists of line
	identifications and intensities. Takes as input the structure created by
	CH_SYNTHETIC. Line emissivities
emiss_calc	To compute the emissivities of all lines of a specified ion over given ranges
gofn+	of temperature and density.
gofnt	Calculates the contribution functions $G(T)$
g_of_t	To compute the G(T) of selected lines.
1 7	Density-sensitive line ratios
dens_plotter	A widget routine to allow the analysis of density sensitive ratios.
density_ratios	Plots the variation of line intensities with electron density
chianti_ne	A widget to calculate and plot density sensitive line ratios.
plot_chianti_ne	Plots density sensitive ratios saved from CHIANTI_NE
	Temperature-sensitive line ratios
temp_plotter	A widget routine to allow the analysis of temperature sensitive ratios.
temperature_ratios	Plots the variation of line intensities with electron temperature .
chianti_te	A widget to calculate and plot temperature sensitive line ratios.
plot_chianti_te	Plots temperature sensitive ratios saved from CHIANTI_TE
	Continuum
freefree	calculates the free-free (bremsstrahlung) continuum.
freebound	calculates the free-bound continuum.
two_photon	calculates the two-photon continuum.
-	Level populations
plot_populations	plots the level populations
pop_plot	To plot $n_i A_i i/N_e$ values as a function of $N_e$ .
show_pops	To display populations of significant levels in a CHIANTI ion model.
pop_processes	Outputs to the screen the contributions of the different physical processes
	to the population of the specified level within an ion.
	Miscellaneous
rad_loss	Calculates the radiative losses
max_temp	Calculates temperature at max ionisation ratio for an ion.
plot_ioneq	Plots the ionisation equilibrium values for an element.
chianti_dem	Calculates the Differential Emission Measure DEM(T) using the CHI-
	ANTI database, from a given set of observed lines.
plot_dem	To plot differential emission measure (DEM) values
integral_calc	To compute the atomic data integral for use in column or volume emission
ch_read_fits	measure work.  Read standard CHIANTI FITS binary table data containing the output
011_1044_1100	from CH_SYNTHETIC and outputs a CHIANTI line intensities structure.

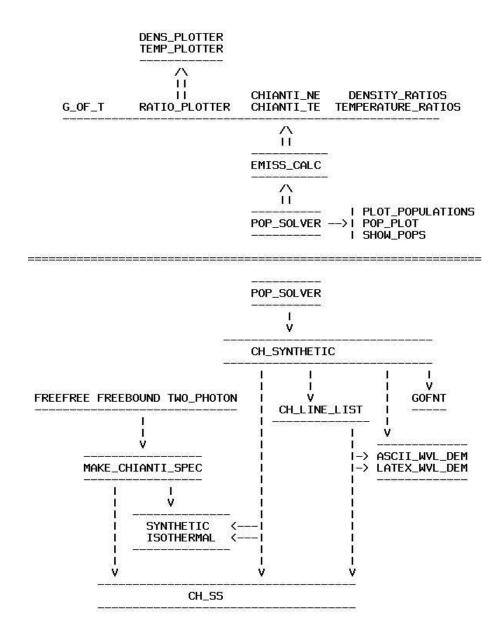

Figure 1: Schematic flow chart showing the main links between the high-level routines. POP\_SOLVER is the core low-level routine that is called by most CHIANTI routines. Note that many CHIANTI routines are now wrapper routines. For example, now DENSITY\_RATIOS calls EMISS\_CALC that in turn calls POP\_SOLVER. SYNTHETIC and ISOTHERMAL are now wrapper routines that call CH\_SYNTHETIC and MAKE\_CHIANTI\_SPEC.

```
Another way to quickly see the keywords of a routine is to use:

IDL > chkarg, 'temperature_ratios
.....
---> Call: pro temperature_ratios,ions,wmin,wmax,tempmin,tempmax,$
temperature,ratio,description,$
density=density,psfile=psfile,$
outfile=outfile,noprot=noprot,$
radtemp=radtemp,rphot=rphot,photons=photons,$
ioneq_file=ioneq_file, abund_file=abund_file,$
VERBOSE=VERBOSE
```

### 7 The CHIANTI distribution and installation

CHIANTI is currently distributed in two ways:

IDL > xdoc,'ch\_synthetic'

IDL > doc\_library,'ch\_synthetic'

1. as an independent package within SolarSoft, a programming and data analysis environment for the solar physics community. See

```
http://www.lmsal.com/solarsoft/
```

for details on how to download and install the package. The database and the software are organised in a self-contained package

```
$SSW/packages/chianti/
```

with the following tree structure:

```
dbase/ (database)
doc/ (documentation, in particular the USER GUIDE)
idl/ (IDL software)
setup/ (supplementary setup files)
```

The contents of the SolarSoft CHIANTI package are mirrored daily from a master tree. Normally, only small fixes to the existing software can occur rather frequently.

All modifications to the software are logged in the \$SSW/packages/chianti/idl/HISTORY file.

Modifications to the database are much less frequent. They are described in the \$SSW/packages/chianti/dbase/README\_CHIANTI file.

We send an e-mail to the CHIANTI user group every time we make a minor release of the database available.

Note that the contents of the SolarSoft package change on a frequent timescale normally to fix bugs caused by the use of new IDL releases.

We recommend that you use CHIANTI within the SolarSoft framework and that you setup in your site a mirror in order to have automatic upgrades. It is easy to follow the instructions to download and setup the package.

- 2. On the WWW, as tar files, via one the WWW CHIANTI pages, e.g.:
  - RAL, UK: http://www.chianti.rl.ac.uk/
  - NRL, USA: http://www.solar.nrl.navy.mil/chianti.html

Currently, the data and the software are distributed in two separate tar files. The tar files have a similar tree structure as the SolarSoft distribution.

E.g. the data are in CHIANTI\_4.0\_data.tar that contains a copy of \$SSW/packages/chianti/dbase.

CHIANTI-4.0\_pro.tar contains doc/, a copy of \$SSW/packages/chianti/doc/ and idl/, a copy of \$SSW/packages/chianti/idl/, plus idl/gen/, a copy of the \$SSW/gen/ routines. This is because some routines of the \$SSW/gen/ directory are needed to run some of the CHIANTI programs.

CHIANTI is a package, in the sense that database and progams are to be used together. The current version of the database must be used with the current version of the programs. Backward compatibility does not always apply.

### 7.1 Installing CHIANTI

To run any CHIANTI IDL procedure, the following is needed:

- Access to the CHIANTI IDL routines. The IDL !PATH should contain the paths to the directories where the CHIANTI IDL procedures are.
- Access to the CHIANTI atomic database and ancillary data. This is done by defining the system variable !xuvtop, that should point to the CHIANTI atomic database top directory.
- The following IDL system variables need to be defined:
  - !xuvtop the top directory for the atomic database
  - !ioneq\_file the default ionization equilibrium file
  - !abund\_file the default elemental abundance file
  - !BCOLOR , !ASPECT

### 7.1.1 Installing CHIANTI within SolarSoft

If you are using SolarSoft you should have the setup already organised so as to have the path of the CHIANTI IDL procedures added to IDL\_PATH, the !xuvtop and the other IDL system variables defined. This is done automatically by using

```
unix> setssw chianti
unix> sswidl
or
unix> sswidl
IDL > ssw_packages,/chianti
```

After this, you will be able to run the CHIANTI routines.

### 7.1.2 Installing CHIANTI independently as a stand-alone

Users of previous versions, please NOTICE:

The procedures to install CHIANTI have changed in small but important ways.

#### Download the CHIANTI files

Download the CHIANTI data tar file (e.g. CHIANTI\_4.0\_data.tar.gz) and the CHIANTI IDL procedures tar file (e.g. CHIANTI\_4.0\_pro.tar.gz) and put the tar files into a directory (for example, /data1/chianti/dbase for the data and /data1/chianti/ for the software) and then do the following:

```
unix> gunzip [file_name].tar.gz
unix> tar xvf [file_name].tar
```

This will copy all the CHIANTI data files into /data1/chianti/dbase and create the /data1/chianti/idl and /data1/chianti/doc/ directories.

### Define the IDL paths and the system variables

There are two ways of doing the above. The first is to define the system variables within IDL, the second is outside IDL. We suggest the first option. Once IDL is started, there are three steps:

```
unix > idl
```

1. add to the IDL PATH the path of where the CHIANTI IDL routines are:

```
Unix: IDL> !PATH = '+/data1/chianti/idl:'+!PATH
Windows: IDL> !PATH = '+C:\data1\chianti\idl;'+!PATH
VMS: IDL> !PATH = '+/data1/chianti/idl,'+!PATH
```

#### 2. IDL> !PATH = EXPAND\_PATH(!PATH)

The '+' and the EXPAND\_PATH are needed since the IDL routines are organised into subdirectories. The second option involves writing (UNIX) the following statement in your /.cshrc (or /.login) file:

```
setenv IDL_PATH /usr/local/rsi/idl_4/lib:+/data1/chianti/idl
```

(assuming you have the main IDL directory in /usr/local/rsi/idl\_4).

```
3. Unix: IDL> use_chianti, '/data1/chianti/dbase' Windows: IDL> use_chianti, 'C:\data1\chianti\dbase'
```

After following the above steps, it will be possible to run the CHIANTI routines from any directory. use\_chianti also allows you to set your default abundance and ionization equilibria files with the abund and ioneq keywords.

Previous CHIANTI users should check the note below.

We suggest that you add the three above calls to your IDL\_STARTUP file (say /.idl\_startup). If this file does not exist then it should be created. In UNIX, this can be done if you add the following line to your .login file:

```
setenv IDL_STARTUP ~/.idl_startup
```

(Note that the changes to the .login file mean that you should do a source ~/.login before running IDL).

Alternatively, you can write the three statements above in a file, say start\_chianti.pro:

```
!PATH = '+/data1/chianti/idl:'+!PATH
!PATH = EXPAND_PATH(!PATH)
use_chianti, '/data1/chianti/dbase'
END
```

and run

```
IDL> .r start_chianti
```

#### Note to previous CHIANTI users:

If you had already defined the CHIANTI system variables before entering IDL or in your IDL STARTUP file you should remove those definitions.

Alternatively, instead of using use\_chianti, '/data1/chianti/dbase', you have to make sure you have in your IDL STARTUP file something like this:

```
!PATH = '+/data1/chianti/idl:'+!PATH
!PATH = EXPAND_PATH(!PATH)
defsysv,'!xuvtop', '/data1/chianti/dbase'
defsysv,'!ioneq_file','/data1/chianti/dbase/ioneq/mazzotta_etal.ioneq'
defsysv,'!abund_file','/data1/chianti/dbase/abundance/cosmic.abund'
defsysv,'!BCOLOR',0
defsysv,'!ASPECT',1.0
```

# 8 Theory and definitions

### 8.1 Optically thin emission lines

For a review on Spectroscopic Diagnostics in the EUV for Solar and Stellar Plasmas see e.g. Mason and Monsignori Fossi (1994).

The intensity  $I(\lambda_{ij})$ , of an optically thin spectral line of wavelength  $\lambda_{ij}$  (frequency  $\nu_{ij} = \frac{c}{h\lambda_{ij}}$ ) is

$$I(\lambda_{ij}) = \frac{h\nu_{ij}}{4\pi} \int N_j A_{ji} dh \quad [\text{ergs cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}]$$
 (1)

where i, j are the lower and upper levels,  $A_{ji}$  is the spontaneous transition probability,  $N_j$  is the number density of the upper level j of the emitting ion and h is the line of sight through the emitting plasma. In low density plasmas the collisional excitation processes are generally faster than ionization and recombination timescales, therefore the collisional excitation is dominant over ionization and recombination in populating the excited states. This allows the low-lying level populations to be treated separately from the ionization and recombination processes.

For allowed transitions we have  $N_j(X^{+m})A_{ji} \sim N_e$ . The population of the level j can be expressed as:

$$N_j(X^{+m}) = \frac{N_j(X^{+m})}{N(X^{+m})} \frac{N(X^{+m})}{N(X)} \frac{N(X)}{N(H)} \frac{N(H)}{N_e} N_e$$
 (2)

- $N(X^{+m})/N(X)$  is the ionization ratio of the ion  $X^{+m}$  relative to the total number density of element X (contained in the files in the ioneq/ directory);
- Ab(X) = N(X)/N(H) is the elemental abundance relative to Hydrogen (contained in the files in the abundance/ directory);
- $N(H)/N_e$  is the Hydrogen density relative to the free electron density. Often assumed to be equal to 0.83, as hydrogen and helium are usually completely ionised for hot optically thin plasmas.

See the routine PROTON\_DENS described in Sect. B.5 for details on how to calculate  $N(H)/N_e$ .

• The fraction  $n_i = \frac{N_j(X^{+m})}{N(X^{+m})}$  of ions  $X^{+m}$  lying in the state j is determined within CHIANTI by solving the statistical equilibrium equations for a number of low-lying levels of the ion including all the important collisional and radiative excitation and de-excitation mechanisms.

In the 'standard model' for interpreting line intensities there are three fundamental assumptions that serve to simplify the problem considerably:

1. the plasma is in a steady state;

- 2. atomic processes affecting the ionisation state of an element can be separated from those affecting the level balance within an ion;
- 3. all lines are optically thin.

The atomic data contained in the CHIANTI database are particularly suited to the analysis of emission lines via this model, and the following discussion outlines this approach. No attempt is made to discuss non-equilibrium conditions.

With the first of the assumptions, the population of ions lying in a given state is constant and so the number of ions leaving this state per unit time must exactly balance the number arriving into that state. If we denote the number of transitions leaving the state i to a state j taking place per unit time per unit volume by  $\alpha_{ij}$ , then steady state implies

$$N_{\rm i} \sum_{\rm j \neq i} \alpha_{\rm ij} = \sum_{\rm j \neq i} N_{\rm j} \alpha_{\rm ji}. \tag{3}$$

Setting

$$\alpha_{ii} = -\sum_{j \neq i} \alpha_{ij} \tag{4}$$

we have

$$\sum_{\mathbf{j}} N_{\mathbf{j}} \alpha_{\mathbf{j}\mathbf{i}} = 0 \tag{5}$$

for each state i and, as the coefficients  $\alpha_{ji}$  are independent of the state populations, we have a set of linear equations to solve for the  $N_i$ .

Now our second assumption means that the processes that affect the ionisation state of the plasma do not affect the quantity  $n_i$ . Eq. 5 thus becomes

$$\sum_{j} n_{j} \alpha_{ji} = 0 \tag{6}$$

where the  $\alpha_{ii}$  only include those processes that affect the level balance of the ion.

For the basic CHIANTI model these processes are simply electron and proton excitation and de-excitation, and the generalised radiative decay:

$$\alpha_{ij} = N_{\rm e}C_{ij}^e + N_{\rm p}C_{ij}^p + \mathcal{A}_{ij} \tag{7}$$

where  $C_{ij}^e$  is the electron excitation—de-excitation rate,  $C_{ij}^p$  is the proton excitation—de-excitation rate,  $N_p$  is the proton density,  $\mathcal{A}_{ij}$  is the generalized radiative decay rate, that includes  $A_{ij}$ , the radiative decay rate which is zero for i<j (the 'A-values' are contained in the CHIANTI .wgfa files), and the photoexcitation and stimulated emission.  $C_{ij}^e$  is given by:

$$C_{ij}^e = N_e q_{ij} \quad i < j \tag{8}$$

$$C_{ij}^e = N_e \frac{\omega_j}{\omega_i} \exp\left(\frac{\Delta E}{kT}\right) q_{ji} \quad i > j$$
 (9)

where  $\omega_i$  is the statistical weight of level i, k is Boltzmann's constant, T the electron temperature, and  $q_{ij}$  the electron excitation rate coefficient which is given by:

$$q_{ij} = 2.172 \times 10^{-8} \left(\frac{I_{\infty}}{kT}\right)^{1/2} \exp\left(-\frac{\Delta E}{kT}\right) \frac{\Upsilon_{ij}}{\omega_i} \qquad [\text{cm}^3 \text{ s}^{-1}]$$
 (10)

where  $I_{\infty}$  is the Rydberg energy (13.61 eV), and  $\Upsilon_{ij}$  is the thermally-averaged collision strength for the  $i \to j$  excitation. The  $\Upsilon_{ij}$  are derived from the scaled data in the CHIANTI splups files.

The solution of Eq. 6 is performed by the CHIANTI routine pop\_solver.pro, which gives the fraction of ions in the state i.

The level populations for a given ion can be calculated and displayed with plot\_populations.pro (but also see pop\_plot.pro).

We rewrite the intensity as:

$$I(\lambda_{ij}) = \int Ab(X)C(T, \lambda_{ij}, N_e)N_eN_H dh$$
(11)

where the function

$$C(T, \lambda_{ij}, N_e) = \frac{h\nu_{ij}}{4\pi} \frac{A_{ji}}{N_e} \frac{N_j(X^{+m})}{N(X^{+m})} \frac{N(X^{+m})}{N(X)} \text{ [ergs cm}^{+3} \text{ s}^{-1}],$$
 (12)

called the *contribution function*, contains all of the relevant atomic physics parameters and is strongly peaked in temperature.

gofnt.pro calculates these contribution functions (see also g\_of\_t.pro for a slightly different way of calculating contribution functions).

Please note that in the literature there are various definitions of contribution functions. Aside from having values in in either photons or ergs, sometime the factor  $\frac{1}{4\pi}$  is not included. Sometimes a value of 0.83 for  $N(H)/N_e$  is assumed and included. Sometimes the element abundance factor is also included. Any of the above (or any other) variations also affect the definition of a line intensity in terms of the contribution function and the DEM. In the following we will refer to the functions  $C(T, \lambda_{ij}, N_e)$  and  $G(T, \lambda_{ij}, Ab(X), N_e) = Ab(X)$   $C(T, \lambda_{ij}, N_e)$  (i.e. the contribution function that contains the abundance factor ).

If we define, assuming that is a single-value function of the temperature, the differential emission measure DEM(T) function as

$$DEM(T) = N_e N_H \frac{dh}{dT} [\text{cm}^{-5} \text{K}^{-1}]$$
 (13)

the intensity can be rewritten, assuming that the abundance is constant along the line of sight:

$$I(\lambda_{ij}) = Ab(X) \int_{T} C(T, \lambda_{ij}, N_e) DEM(T) dT \text{ [ergs cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}]$$
 (14)

The DEM gives an indication of the amount of plasma along the line of sight that is emitting the radiation observed and has a temperature between T and T + dT.

The IDL routine chianti\_dem.pro described in Sect. 9.16 calculates the Differential Emission Measure DEM(T) using the CHIANTI database, from a given set of observed lines.

Routines such as ch\_synthetic.pro (see Sect. 9.1 and Sect. ??) calculate line intensities without the abundance factor, that is only included at a later stage.

In the isothermal approximation, all plasma is assumed to be at a single temperature  $(T_o)$  and the intensity becomes:

$$I(\lambda_{ij}) = C(T_o, \lambda_{ij}, N_e)Ab(X)EM_h \tag{15}$$

where we have defined the column emission measure

$$EM_h = \int N_e N_H dh \quad [\text{cm}^{-5}] \tag{16}$$

ch\_synthetic.pro in the isothermal approximation calculates  $I = C(T_o, \lambda_{ij}, N_e) \int N_e N_H dh$ , while isothermal.pro and ch\_ss.pro (see examples in Sect. 9.1) can be used to create synthetic spectra (with the abundance factor).

It is also possible to calculate intensities and spectra with a multi-temperature model, by providing an array of  $T_o$ ,  $EM_h$  values.

Please note that in the literature many different definitions of Differential Emission Measures, Emission Measures and approximations can be found (see Del Zanna et al., 2002 for some clarifications).

#### 8.1.1 The stellar case

In the stellar case, the theoretical flux of an optically thin spectral line is:

$$F(\lambda_{ij}) = \frac{1}{d^2} \int_V Ab(X) C(N_e, T, \lambda_{ij}) N_e N_H dV \text{ [ergs cm}^{-2} \text{ s}^{-1}]$$
 (17)

where  $C(N_e, T, \lambda_{ij})$  has the same expression as above, d is the star's distance, dV is the volume element, and V is the entire source volume. A **volume** Differential Emission Measures DEM is often defined:

$$DEM(T) = N_{\rm e}N_{\rm H}\frac{dV}{dT} \ \left[\text{cm}^{-3}\text{K}^{-1}\right] \tag{18}$$

together with a corresponding volume emission measure  $EM_V$ :

$$EM_V = \int N_e N_H dV \quad [\text{cm}^{-3}] \tag{19}$$

At the moment CHIANTI does not include volume emission measures. In the near future we will modify the software and the definition of the DEM in order to include volume emission measures.

However, any **volume** Differential Emission Measures can be rescaled to **column** DEMs and used within the software to produce synthetic spectra for stellar coronae. One way of doing this is to assume spherical symmetry, and that the emitting region is a layer dh distributed over the entire star's disk, i.e.  $dV = 4\pi R_*^2 dh$  ( $R_*$  is the star's radius). If the star's radius and distance are known, a **volume** DEM can be scaled with the factor  $\frac{4\pi R_*^2}{d^2}$  to obtain a **column** DEM.

If this is used, the outputs will have flux units, i.e.  $ergscm^{-2}s^{-1}$  (or  $photonscm^{-2}s^{-1}$ ) and **not**  $ergscm^{-2}s^{-1}sr^{-1}$ .

An example of scaled DEM is provided in the file AU\_Mic.dem, in the CHIANTI distribution.

Column DEMs and EMs are assumed when the spectra are folded with effective areas (see Sect. 9.1). The effective areas are assumed to have units of  $countsphotons^{-1}cm^{+2}$ , so the output units of the spectra will be  $countss^{-1}pixel^{-1}$ .

Also note that corrections to **interstellar absorption** are not presently included in CHI-ANTI.

### 8.2 Proton rates

For each ion for which proton rates are available, an additional file is required in the database to contain the fits to the rate coefficients. The file has the suffix .PSPLUPS, and is exactly analogous to the .SPLUPS file for the electron fits. All of the proton transitions included in CHIANTI are forbidden transitions taking place between levels within the same configuration. Many of the transitions required 9-point splines (see Sect. C) in order to provide adequate fits. The number density of protons,  $N_{\rm p}$ , is calculated with the IDL routine proton\_dens.pro (see Sect. B.5).

By default, all routines will include proton rates in the calculation of the ion level balance. A keyword /NOPROT can be used to switch off the proton rates.

### 8.3 Non-Maxwellian particle distributions

Within CHIANTI the assumption of Maxwellian electron and proton distributions is implicit through the storage of Maxwellian-averaged electron and proton collision strengths in the .SPLUPS and .PSPLUPS data files. To model emission from plasmas with general, non-Maxwellian particle distributions would require integrations of the original collision strengths with the new particle distributions, and this is outside of the scope of the CHIANTI database. However, if the particle distributions can be expressed as a linear combination of Maxwellians of different temperatures, i.e.,

$$f(E; a_i) = \sum_i a_i f_M(E, T_i)$$
(20)

where the Maxwellian function  $f_M(E, T_i)$  is given by

$$f_M(E, T_i) = 2\left(\frac{E}{\pi}\right)^{1/2} \left(\frac{1}{kT}\right)^{3/2} \exp\left(-\frac{E}{kT}\right)$$
(21)

then such distributions can be modelled in a straightforward manner within the CHIANTI framework.

The generalized electron excitation rate coefficient for the transition j to k and for the particle distribution f of electron velocities is given by

$$C_{jk} = \int_{E_{jk}}^{\infty} Q_{jk} v f(E; a_i) dE$$
 (22)

$$= \sum_{i} a_i \int_{E_{jk}}^{\infty} Q_{jk} v f_{\mathcal{M}}(E, T_i) dE$$
 (23)

$$= \sum_{i} a_i C_{jk}(T_i) \tag{24}$$

where  $E_{jk}$  is the threshold energy for the transition,  $Q_{jk}$  is the collision cross section, E (=  $m_e v^2/2$ ,  $m_e$  the electron mass) is the energy of the incoming electron, and  $C_{jk}(T_i)$  is the electron excitation rate coefficient for a Maxwellian particle distribution of temperature  $T_i$  (see, e.g., Burgess & Tully 1992).

The matrix  $C_{jk}$  replaces the usual Maxwellian-derived rate coefficient  $(C_{jk})$  in the level balance equations solved by the CHIANTI software. The software routines for calculating emissivities and level populations have been modified to allow input of the non-Maxwellian parameters  $a_i$  through the keyword SUM\_MWL\_COEFFS. The temperatures  $T_i$  are specified through the standard temperature input to the routines. The temperatures are assumed to apply to both proton and electron distributions.

This prescription for treating non-Maxwellian distributions is not compatible with the treatment of ionization and recombination since an equilibrium ionization balance described by a single temperature is required for these processes. In such cases the ionization and recombination processes described in Sect. ?? are switched off when calculating the level populations if the  $a_i$  coefficients are specified in CHIANTI.

See Sect. 9.8 for an example.

### 8.4 Photoexcitation and Stimulated Emission

Within CHIANTI, we presently model the Photoexcitation and Stimulated Emission by assuming a blackbody radiation field of temperature  $T_*$ . The generalized photon rate coefficient in this case is:

$$\mathcal{A}_{ij} = \begin{cases} W(R) A_{ji} \frac{\omega_j}{\omega_i} \frac{1}{\exp(\Delta E/kT_*) - 1} & i < j \\ A_{ji} \left[ 1 + W(R) \frac{1}{\exp(\Delta E/kT_*) - 1} \right] & i > j \end{cases}$$
 (25)

where  $A_{ji}$  is the radiative decay rate and W(R) is the radiation dilution factor which accounts for the weakening of the radiation field at distances R from the source center.

We also assume an uniform (no limb brightening/darkening) spherical source with radius  $R_*$ :

$$W = \frac{1}{2} \left[ 1 - \left( 1 - \frac{1}{r^2} \right)^{1/2} \right] \tag{26}$$

where

$$r = \frac{R}{R_{\rm c}} \tag{27}$$

It is important to remember the assumptions in our formalism for radiation processes. For a given ion, only very specific wavelengths in the radiation continuum will affect the ion's level balance. If there are significant deviations from a blackbody spectrum at any of these wavelengths (perhaps due to a deep absorption line) then CHIANTI does not model the ion entirely correctly.

Examples of specific uses of the extra radiation processes include modeling of coronal emission lines above the surface of the Sun and other cool stars when the coronal electron density falls to low enough values that electron collisions lose their potency.

For the Sun, photoexcitation is very important for the infrared coronal lines. Photoexcitation is also important for modelling nebular ions that are irradiated by a hot star, such as in planetary nebulae, symbiotic stars and Wolf-Rayet stars.

### 8.4.1 Implementation of Photoexcitation and Stimulated Emission

No additions or modifications to CHIANTI data files are required for photoexcitation and stimulated emission as their rates are entirely determined from the radiative decay rates, level separation energies, and statistical weights – information already contained in CHIANTI. It is only necessary to specify the radiation field temperature and the dilution factor. These are specified as inputs to the IDL procedures through the new keywords RPHOT and RADTEMP. RPHOT specifies  $r = \frac{R}{R_*}$ , while RADTEMP gives the blackbody radiation temperature in K.

By default, photoexcitation and stimulated emission are not included in the level balance equations unless the keywords are set.

### 8.5 Photoexcitation by arbitrary radiation fields

Version 4 of CHIANTI introduced the possibility of including photoexcitation and stimulated emission through an external blackbody radiation field into the level balance equations. With version 5 the software has been modified to allow an arbitrary, user-defined radiation field to be specified.

The user must create an IDL routine that calculates the energy density per unit wavelength,  $U_{\lambda}$ , as a function of wavelength. The photoexcitation rate for a transition  $i \to j$  is related to  $U_{\lambda}$  by the expression

$$P_{ij} = A_{ji}W(R)\frac{\omega_j}{\omega_i}\frac{\lambda^5}{8\pi\hbar c}U_{\lambda}$$
 (28)

where W(R) is the dilution factor defined as in Young et al. (2003),  $A_{ji}$  is the Einstein coefficient for spontaneous radiation from j to i,  $\omega_j$  and  $\omega_i$  are the statistical weights of levels j and i. or example,  $U_{\lambda}$  for a blackbody of temperature, T, is given by

$$U_{\lambda}^{\text{bb}} = \frac{8\pi hc}{\lambda^5} \frac{1}{\exp(hc/\lambda kT) - 1} \tag{29}$$

thus giving the photoexcitation rate for a blackbody of

$$P_{ij}^{\text{bb}} = A_{ji}W(R)\frac{\omega_j}{\omega_i}\frac{1}{\exp(E/kT) - 1}$$
(30)

For reference we note that the energy density is related to the specific intensity,  $I_{\lambda}$ , by

$$I_{\lambda} = \frac{c}{4\pi} U_{\lambda}.\tag{31}$$

The user-defined radiation field function is implemented through a keyword RADFUNC='user\_function, a, b' in the CHIANTI IDL routines SHOW\_POPS and EMISS\_CALC. The optional coefficients a and b can be used to modify the radiation field, e.g., by specifying a relative velocity between the radiation field and incident ion. See Sect. 9.7 for an example.

#### 8.6 Ionization and recombination

In Version 5 of CHIANTI, we have included ionization and recombination into level populations. The CHIANTI model for ionization and recombination assumes that the plasma can be described under the Coronal Model Approximation, where the total population of the excited levels of an ion is negligible compared to the population of the ground level. In this case, recombination and ionization processes can be included in a relatively straightforward way, since they can be treated as a correction to the case where populations are calculated neglecting them.

To illustrate this method, we will consider the simplified atomic model of an ion  $X^{+q}$  with abundance  $n_q$  composed of the ground level and one excited level only. In case ionization and recombination contributions to level populations are negligible, the relative population of the upper level is obtained by solving the equation:

$$N_g N_e C_{g \to i} = N_i A_{i \to g} \qquad \Longrightarrow \qquad \left(\frac{N_i}{N_g}\right)_{ion/rec} = \frac{N_e C_{g \to i}}{A_{i \to g}}$$
 (32)

where  $C_{g\to i}$  is the collisional excitation rate and  $A_{i\to g}$  is the Einstein coefficient for spontaneous radiative decay. Collisional de-excitation is neglected in the coronal model approximation. In case ionization and recombination provide significant contribution, Equation 32 needs to be modified to include the rate coefficients for ionization  $(\alpha_{ion})$  and recombination  $(\alpha_{rec})$ :

$$N_g N_e (n_q C_{g \to i} + n_{q-1} \alpha_{ion} + n_{q+1} \alpha_{rec}) = N_i A_{i \to g} n_q$$
(33)

where  $n_{q-1}$ ,  $n_q$ ,  $n_{q+1}$  are the ion fractions for the ions  $X^{q-1}$ ,  $X^q$  and  $X^{q+1}$ , respectively. The population of the excited level can then be expressed as

$$\left(\frac{N_i}{N_g}\right)_{ion/rec} = \left(\frac{N_i}{N_g}\right)_{no\ ion/rec} \times \aleph$$
(34)

where the correction  $\aleph$  is given by

$$\aleph = 1 + \frac{n_{q-1}\alpha_{ion} + n_{q+1}\alpha_{rec}}{n_q C_{q \to i}}$$
(35)

The correction  $\aleph$  is temperature sensitive and can be large when the collisional excitation rate is small or when the abundance of the ion q is much smaller than the abundances of the adjacent ions. The correction due to ionization and recombination can have significant effects on intensities of observed X-ray lines.

The only limitation of this approach lies in the breakdown of the coronal model approximation at high densities for a few ions. This occurs at densities above which metastable level populations begin to be non-negligible, compared to the ground state (cf. Landi et al. 2005). The CHIANTI software has been modified to allow calculation of the correction factor  $\aleph$  for the ions for which  $\alpha_{ion}$  and  $\alpha_{rec}$  are provided.

The inclusion of ionization and recombination effects in level population has required some more changes. New files have been created (.CILVL and .RECLVL) to store the ionization and recombination rates necessary for this process (see Sect. 5.1.1 for details).

A new routine (READ\_IONREC.PRO) has been created to read these files and store their data in the input to the routine POP\_SOLVER.PRO. This latter routine has been modified to include the correction to the level populations. In case the .CILVL and .RECLVL files are not available, a flag is set in the programs and these processes are ignored. The impact of this new process on the running time is negligible.

However, the introduction of ionization and recombination effects on level population has had a side effect. In previous versions of CHIANTI, the contribution to the intensity of spectral lines from levels below the ionization potential due to cascades from levels above the ionization potential was taken into account in the "dielectronic" .WGFA files, which included radiative transitions from the former, populated by cascades from the latter. For the ions for which the complete .RECLVL and .CILVL files are now available (Fe XVII to Fe XXIV), cascades from levels above ionization are now taken into account directly, so that the cascade contribution calculated by the "dielectronic" .WGFA files is not anymore necessary. To avoid double-counting this contribution, the transitions from levels below the ionization threshold in the "dielectronic" .WGFA files have been given a null wavelength, so they can be removed from the spectrum without having to change the way the "dielectronic" level population are handled.

#### 8.7 Continuum calculations

An IDL routine to include the two photon continuum has been added to CHIANTI, while the free-bound and free-free continuum (bremsstrahlung) routines have been revised. See Young et. al. (2002) for more details.

Note that the output units of the continuum routines are by default  $10^{-40}$  ergs sr<sup>-1</sup> s<sup>-1</sup> Å<sup>-1</sup> per unit emission measure  $\int N_e N_H dh$ .

On the other hand, the SolarSoft routine CONFLX outputs a continuum in photons s<sup>-1</sup> Å<sup>-1</sup> assuming an emission measure  $\int N_e^2 dh = 10^{50}$ .

#### 8.7.1 Two photon continuum

The two-photon continuum is calculated with two\_photon.pro.

#### Transitions in hydrogen-sequence ions

The first excited level  $(2s \ ^2S_{1/2})$  of the hydrogen iso-electronic sequence ions can decay only by means of forbidden magnetic dipole and two-photon transitions. The importance

of the competing magnetic dipole transition increases with Z but for nickel (Z=28), the two-photon transition rate is roughly 5 times that of the magnetic dipole rate.

The spectral emissivity (erg cm<sup>-3</sup> s<sup>-1</sup> sr<sup>-1</sup> Å<sup>-1</sup>) for optically-thin two-photon emission at wavelength  $\lambda$  is given by:

$$\frac{d\epsilon_{i,j}}{d\lambda} = \frac{hc}{4\pi\lambda} A_{ji} N_j(X^{+m}) \phi(\lambda_0/\lambda)$$
(36)

where  $A_{j,i}$  (sec<sup>-1</sup>) is the Einstein spontaneous emission coefficient (A value);  $N_j(X^{+m})$  is the number density of the level j of the ion  $X^{+m}$ ;  $\phi$  is the spectral distribution function; and  $\lambda_0$  is the wavelength corresponding to the energy difference between the excited and ground level.

### Two-photon continuum transitions in helium-sequence ions

For the helium iso-electronic sequence, the second excited level  $(1s2s \ ^1S_0)$  decays through a forbidden magnetic dipole and two-photon transitions.

### 8.7.2 Bremsstrahlung

The bremsstrahlung emission is calculated with freefree.pro. This routine has been rewritten ex-novo. It now includes the Itoh et al. (2000) and Sutherland (1998) gaunt factors. Itoh et al. (2000) have provided an analytical fitting formula for the relativistic thermal bremsstrahlung gaunt factors, and this is now added to CHIANTI. The fitting formula is valid for the ranges  $6.0 \le \log T \le 8.5$  and  $-4.0 \le \log (hc/k\lambda T) \le 1.0$ . For temperatures below  $\log T = 6.0$  we retain the non-relativistic Gaunt factors of Sutherland (1998) for computing the continuum. The condition  $\log (hc/k\lambda T) \le 1.0$  results in some of the low wavelength points being inaccurately represented by the Itoh et al. fitting formula. For these wavelengths the Gaunt factors of Sutherland (1998) are used to compute the continuum level. The relativistic free-free continuum is almost identical to the non-relativistic continuum at low temperatures. At  $T = 1 \times 10^8$  K (the maximum temperature permitted by the ion balance calculations contained in CHIANTI) the relativistic continuum is around 1% higher near the peak of the distribution.

#### 8.7.3 Free-bound continuum

The free-bound continuum emission is calculated with freebound.pro. This routine has been rewritten. The new routine uses the the Karzas and Latter (1961) approximation to the photoionization cross-sections and calculates free-bound gaunt factors for levels n=1-6. Additional data files have been created for this purpose. For example, free-bound radiation produced by recombination of an electron onto C IV to produce C III will use the data in the c\\_3.fblvl file.

# 9 Some examples on how to use the software

In what follows we review the main points about the new software. We hope you find it useful and enjoy using it!

### 9.1 Calculating line intensities.

For an user-friendly, widget-based approach the best option is to use CH\_SS:

```
IDL >ch_ss
```

This widget allows the user to calculate synthetic spectra in two basic steps. Basically, you follow the various widgets from top left to lower right to set the desired parameters. First calculate the line intensities. These values can be saved for later use. Next, specify further parameters such as the elemental abundances and instrumental spectral resolution and then calculate and plot the spectrum. These values can also be saved for later use. The HELP buttons in the widget provide short descriptions of the required information. More details are given below.

Alternatively, for e.g. background jobs, the routine CH\_SYNTHETIC can be used. ch\_synthetic.pro calculates line intensities assuming constant pressure or density (or a model T,N), without the abundance factor. One of the reasons why element abundances are not included in the line intensities calculation is so that it is easier for the user to see how modifying abundances affects their spectra in e.g. ch\_ss.pro. The calling sequence is:

```
IDL> ch_synthetic, wmin, wmax, output=output, err_msg=err_msg, msg=msg, $
    pressure=pressure, density=density, $
    model_file=model_file, all=all,sngl_ion=sngl_ion, $
    photons=photons, masterlist=masterlist, $
    save_file=save_file , verbose=verbose,$
    logt_isothermal=logt_isothermal, logem_isothermal=logem_isothermal,$
    goft=goft, ioneq_name=ioneq_name, dem_name=dem_name, $
    noprot=noprot, rphot=rphot, radtemp=radtemp, progress=progress
```

The routine has many KEYWORDS (see Sect. ?? for a full list) A series of parameters must be set:

- Wmin, Wmax: minimum maximum of the desired wavelength range in Angstroms
- The (Te,Ne) model for the calculation:

```
Pressure: pressure in emitting region (Pe, cm^-3 K).

Only a single value is accepted, and the calculation is performed at constant pressure.
```

```
Density: density in emitting region (Ne, cm^-3).

Only a single value is accepted, and the calculation is
```

performed at constant density, unless LOGT\_ISOTHERMAL is defined. In this case, DENSITY can be an array of values, but has to have the same number of elements as LOGT\_ISOTHERMAL.

model\_file Full path of the (Te,Ne) file if defined.

This file should have two columns, one with the Te (K) values, and one with the Ne (cm^-3) values. If these values are not sorted in ascending order of Te, the routine does sort them.

- IONEQ\_NAME: The ionization fraction file to be used. The program will prompt the user to select one if not defined.
- OUTPUT: The name of the structure containing the line intensities and details.

The line intensities are calculated either in the isothermal approximation, in which case the following has to be defined:

```
LOGT_ISOTHERMAL: Array of logarithmic temperatures.

LOGEM_ISOTHERMAL: Array of logarithmic emission measures (0 by default).
```

or by folding the G(T) with a differential emission measure DEM contained in the file specified by DEM\_NAME. The program will prompt the user to select one if not defined. **Example:** 

```
IDL> ch_synthetic, 10,20., output=str , pressure=1.e+15,$
    ioneq_name=concat_dir(concat_dir(!xuvtop,'ioneq'),'mazzotta_etal.ioneq'),$
    dem_name=concat_dir(concat_dir(!xuvtop,'dem'),'flare.dem'),$
    /photons, /noprot, /all, sngl_ion=['fe_17','fe_18']
```

Creates an output structure str that contains the line intensities of only Fe XVII and Fe XVIII in the 10–20 Å range calculated at constant pressure of  $10^{15}$ , with the ionization balance in mazzotta\_etal.ioneq and the DEM values in flare.dem in the standard CHI-ANTI distribution (if not supplied these files can be selected with a widget). Line intensities are in photons cm<sup>-2</sup> s<sup>-1</sup> sr<sup>-1</sup> (KEYWORD photons), the proton rates are not included (KEYWORD noprot), and all the lines in the database (KEYWORD all) are included (also the lines with only theoretical energy levels).

You can see the contents of the structure with e.g.

```
IDL> help, str,/st
IDL> help, str.lines[0],/st
```

The last command shows the first structure associated with the first spectral line.

# 9.2 Saving, restoring and exporting the CHIANTI line intensities structure

The CHIANTI line intensities structure can be saved and later restored from the command line in various ways. We suggest two:

1. as IDL binary files using the SolarSoft routines:

```
IDL> savegen, file='ch_int_10_20_fe.genx', struct=str
IDL> restgen, file='ch_int_10_20_fe.genx', struct=str
```

to save and restore the IDL structure str in the file ch\_int\_10\_20\_fe.genx.

Please note that we discourage the use of e.g.:

```
IDL> save, file='output.save', output
IDL> restore, file='output.save'
```

since IDL save files generated with later versions of IDL are usually not readable with earlier versions.

2. as FITS binary tables, that can be easily exported and read by different platforms. We have written two IDL routines:

```
IDL> ch_write_fits, str, 'output.fits'
IDL> ch_read_fits,'output.fits', str
```

to save and restore the IDL structure str in the FITS file output.fits. Aside from an introductory HEADER, the contents of the IDL structure are converted into two binary tables. Extensive comments are added.

In either case, the structure saved in the <code>.genx</code> and <code>.fits</code> files can be restored via CH\_SS to later create a spectrum.

### 9.3 Create a latex or ascii file with all the line details

For an user-friendly approach the best option is to use CH\_SS:

```
IDL >ch_ss
```

Alternatively, if you have already calculated a line intensity structure (as shown above), you can use CH\_LINE\_LIST. This program creates a latex or an ascii file of predicted spectral line intensities and wavelengths corresponding to selected parameters.

The routine has many KEYWORDS. Please read the header or read Sect. ?? for details. The calling sequence is:

```
IDL> ch_line_list, transitions, outname, latex=latex, ascii=ascii, $
    wmin=wmin,wmax=wmax,$
    SPECTRUM=SPECTRUM, abundfile=abundfile, min_abund=min_abund, $
    minI=minI,photons=photons,kev=kev, $
    all=all,no_sort=no_sort, sngl_ion=sngl_ion
```

#### Example:

```
IDL> restgen, file='ch_int_10_20_fe.genx', struct=tran
IDL> ch_line_list, tran, 'ch_line_list.tex', /latex,$
    abundfile=concat_dir(concat_dir(!xuvtop,'abundance'),'cosmic.abund'),$
    mini=1e13
```

This creates a latex file ch\_line\_list.tex where only lines with an intensity greater than 10<sup>13</sup> (KEYWORD mini) are included, and the allen.abund file in the standard CHIANTI distribution is used (if not supplied it can be selected with a widget).

Then, you have to latex the file three times, and optionally xdvi it:

```
unix> latex ch_line_list
unix> latex ch_line_list
unix> latex ch_line_list
unix> xdvi ch_line_list
```

If you do not have it already, you will need the package longtable.sty that is distributed as part of ftp://cam.ctan.org/tex-archive/macros/latex/required/tools.tar.gz
You will obtain a table that looks like:

Ion	$\lambda$ (Å)	Transition	$T_{\rm max}$	Int
Fe XVII	12.1227	$2p^6 {}^1S_0 - 2p^5 4d {}^1P_1$	6.9	1.11e+14
Fe XVII	12.2639	$2p^{6} {}^{1}S_{0} - 2p^{5} 4d {}^{3}D_{1}$	6.9	$9.81e{+13}$
Fe XVII	13.8231	$2p^{6} {}^{1}S_{0} - 2s \ 2p^{6} \ 3p \ {}^{1}P_{1}$	6.9	6.25e + 13
Fe XVIII	13.9540	$2s^2 2p^5 {}^2P_{3/2}$ - $2p^4 ({}^1S) 3d {}^2D_{5/2}$	6.9	2.06e + 13
Fe XVIII	14.1519	$2s^2 2p^5 {}^2P_{3/2} - 2p^4 ({}^1D) 3d {}^2D_{3/2}$	6.9	1.35e + 13

Table 2: Line List

Alternatively, you can also create a latex file with a list of line identifications and intensities using the wrapper routine LATEX\_WVL\_DEM:

```
IDL > latex_wvl_dem,100.,200., pressure=1.e+15,mini=1.
```

However, latex\_wvl\_dem calls ch\_synthetic and ch\_line\_list, and if you want to modify some of the parameters of ch\_line\_list (e.g. the minimum intensity) you will have to redo the calculation which will take some time. Windows will pop up so that you can select the abundance, the ionization equilibrium and the differential emission measure files. This will create by default a file linelist.tex in the user's working directory, by default.

To create an ascii file with the line details you can follow a similar approach, i.e.:

```
IDL> restgen, file='ch_int_10_20_fe.genx', struct=tran
IDL> ch_line_list, tran, 'ch_line_list.ascii', /ascii,$
    abundfile=concat_dir(concat_dir(!xuvtop,'abundance'),'allen.abund'),$
    mini=1e13
```

Alternatively, you can also use the wrapper routine

```
IDL > ascii_wvl_dem,100.,200.,pressure=1.e+15,mini=1.
```

However, ascii\_wvl\_dem calls ch\_synthetic and ch\_line\_list, and if you want to modify some of the parameters of ch\_line\_list (e.g. the minimum intensity) you will have to redo the calculation which will take some time.

## 9.4 Calculating continuum intensities

For example, to calculate the free-free, free-bound and two-photon continuum at a temperature of  $5 \times 10^6$  K, for wavelengths at 1 Å intervals between 1 and 50 Å:

```
freefree,5.e+6,findgen(50)+1.,ff
freebound,5.e+6,findgen(50)+1.,fb
two_photon,5.e+6,findgen(50)+1.,tp
window,0
plot,findgen(50)+1.,ff+fb+tp,xtit='Wavelength (A)'
oplot, findgen(50)+1.,ff,line=2
oplot, findgen(50)+1.,fb,line=3
oplot, findgen(50)+1.,tp,line=4
```

Note that the intensities are in units of  $10^{-40}$  ergs cm<sup>3</sup> s<sup>-1</sup> sr<sup>-1</sup> Å<sup>-1</sup> per unit emission measure  $\int N_{\rm H} N_{\rm e} dh \ ({\rm cm}^{-5})$ .

If DEM values are passed to the routines (via the keyword DEM\_INT), it is assumed that they are given as  $N_{\rm H}N_{\rm e}dh/dT$ . The units are  $10^{-40}$  ergs cm<sup>-2</sup> s<sup>-1</sup> sr<sup>-1</sup> Å<sup>-1</sup> in this case.

# 9.5 Creating a synthetic spectrum with the continuum

The structure created by CH\_SYNTHETIC can be restored via CH\_SS to create a spectrum. Alternatively, it can be used as an input to the program MAKE\_CHIANTI\_SPEC. This program creates the **CHIANTI SPECTRUM structure** (read Sect. E.2 for details), an OUTPUT structure similar to the structure created by CH\_SYNTHETIC, with some additional tags. The calling sequence is:

```
IDL> make_chianti_spec, TRANSITIONS, LAMBDA, OUTPUT, BIN_SIZE=BIN_SIZE, $
    INSTR_FWHM=INSTR_FWHM, BINSIZE=BINSIZE, $
    WRANGE=WRANGE, ALL=ALL, continuum=continuum, $
    ABUND_NAME=ABUND_NAME, MIN_ABUND=MIN_ABUND, $
    photons=photons, file_effarea=file_effarea, $
    err_msg=err_msg, verbose=verbose
```

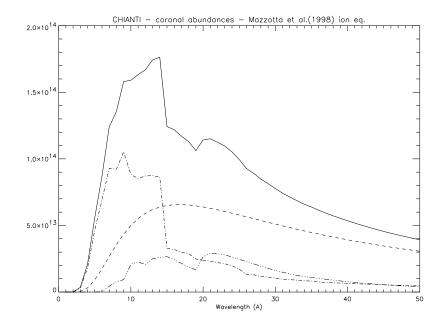

Figure 2: Continuum in the 1-50 Å range.

The routine has many keywords and options. Please read Sect. ?? for details.

```
IDL> restgen, file='ch_int_10_20_fe.genx', struct=tran
IDL> make_chianti_spec, tran, lambda, struct,/CONTINUUM, $
   BIN_SIZE=0.01, instr_fwhm=0.1, WRANGE=[10.,19.],$
   abund_name=concat_dir(concat_dir(!xuvtop,'abundance'),'cosmic.abund')
```

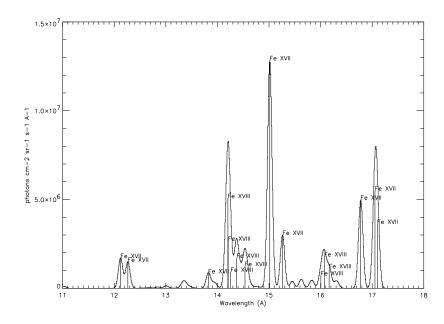

Figure 3: Synthetic spectrum created by MAKE\_CHIANTI\_SPEC.

#### **Some Caveats:**

You may find that the calculation is slow. This is usually due to the continuum calculation. In general, it is advisable not to calculate spectra over large wavelength ranges. In any case you can speed up the continuum calculation by reducing the numbers of elements, using the KEYWORD MIN\_ABUND.

To see the contents of the structure:

```
IDL> help, struct,/st
IDL> help, struct.lines[0],/st
```

While to show the spectrum and the main contributing lines:

It may be useful to save the SPECTRUM structure, that can be later inspected with the widget CH\_SS:

```
IDL> savegen, file='ch_spectrum_10_20_fe.genx', struct=struct
IDL> ch_write_fits, struct, 'ch_spectrum_10_20_fe.fits'
```

Alternatively, the wrapper routine SYNTHETIC (see Fig 1) can also be used to calculate CHIANTI line intensities. For example:

```
IDL > synthetic, 150., 200., 1., pressure=1.e+15, wvl, spectrum, list_wvl, list_ident
```

will create a synthetic spectrum with a resolution of 1 Å between 150 and 200 Å for a specified set of abundances and differential emission measure at a constant pressure of 1.e+15 (N<sub>e</sub> T cm<sup>-3</sup> K). The output arrays wvl, spectrum contain the wavelengths and the intensities (in erg cm<sup>-2</sup> s<sup>-1</sup> sr<sup>-1</sup> Å<sup>-1</sup> by default). The output arrays ist\_wvl, list\_ident contain the list of wavelengths and descriptions of the lines that made up the spectrum.

Windows will pop up so that the user can select the abundance file, the ionization equilibrium and the differential emission measure. A spectrum is created by convolving with a Gaussian profile with a FWHM of 1 Å. If the /CONTINUUM keyword had been set, then the continuum would also have been calculated and added to the spectrum. To plot the spectrum and interactively identify lines:

```
IDL > synthetic_plot, wvl, spectrum, list_wvl, list_ident, 2.
```

by clicking the left mouse button, a list of predicted lines within 2 Å of the selected wavelength will be printed out along with their predicted intensity. Clicking the right mouse button will exit the procedure.

#### 9.5.1 Create a spectrum in the isothermal approximation

For an user-friendly approach the best option is to use CH\_SS:

```
IDL >ch_ss
```

Alternatively:

```
IDL > isothermal, 150., 200., 1., [1.e6], wvl, spectrum,$
    list_wvl, list_ident, edensity=1.e9,$
    ioneq_name=!xuvtop+'/ioneq/mazzotta_etal.ioneq',$
    abund_name=!xuvtop+'/abundance/cosmic.abund'
```

```
IDL> synthetic_plot, wvl, spectrum, list_wvl, list_ident, 1.
```

calculates an isothermal synthetic spectrum with a resolution of 1 Å between 100 and 200 Å for a specified set of abundances and differential emission measure at a constant density  $N_e = 10^9 \text{ cm}^{-3}$ . The output arrays wvl, spectrum contain the wavelengths and the intensities (in erg cm<sup>-2</sup> s<sup>-1</sup> sr<sup>-1</sup> Å<sup>-1</sup> by default). The output arrays ist\_wvl, list\_ident contain the list of wavelengths and descriptions of the lines that made up the spectrum. synthetic\_plot can then be used to view the spectrum.

Note: isothermal now is a wrapper routine that calls ch\_synthetic. It has particular features. Please read the header documentation.

# 9.6 The user-friendly multi-purpose widget ch\_ss.pro

CH\_SS is an user-friendly multi-purpose (see Fig 1) widget that allows the calculation of line intensities (calling CH\_SYNTHETIC) and of a synthetic spectrum (calling MAKE\_CHIANTI\_SPEC) by merging line intensities and continua. The parameters can be interactively set, and the results visually inspected. Line intensities can be saved and restored in various ways. The results can also be stored in various ways, ranging from output plots to tables of line details (using CH\_LINE\_LIST) or save files.

CH\_SS replaces the CHIANTI\_SS procedure. The calling sequence is:

```
IDL> ch_ss, font=font
```

Note that if the widget appears too large you can change the font. The widget is organised into four Sections:

#### 9.6.1 SECTION 1 - The Calculation of the CHIANTI line intensities.

This can be done in two ways:

1-Restore a save file with the CHIANTI line intensities already calculated. This is done with the RESTORE button. .genx and .fits files can be restored.

2-Calculate CHIANTI line intensities with a call to CH\_SYNTHETIC.

In this case, A series of parameters must be set:

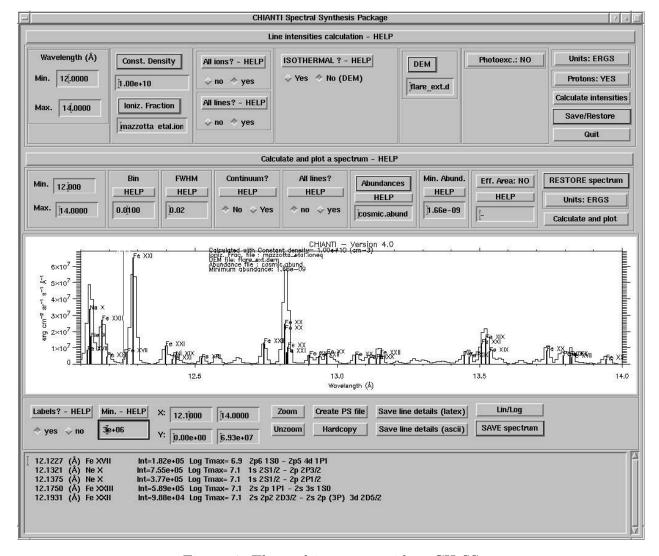

Figure 4: The multi-purpose widget CH\_SS

- - Minimum and maximum wavelengths in Angstroms
- - The model used for the calculation. Three are the options: 1) a constant density (cm<sup>-3</sup>) 2) a constant pressure (cm<sup>-3</sup> K) 3) a general (Te,Ne) model. In this case, a file will be read. This file should have two columns, one with the Te (K) values, and one with the Ne (cm<sup>-3</sup>) values.
- - The ionization fraction file to be used. "\*.ioneq" files can be selected from either the CHIANTI database, the working directory or selected via a widget.
- - All ions ? If set to yes (default), then all the ions present in the database will be included.

If set to no, then it is possible to select a list of ions with a widget

• - All lines? If set to no (default), only the lines for which there are observed energy levels are included

If set to yes, also the lines that do not have corresponding observed energy levels are included. In this case, the wavelengths are calculated from the theoretical energy levels, and might not be very accurate.

• - Isothermal? If set to no (default), a DEM file must be selected. "\*.dem" files (i.e. files with a .dem extension) can be selected from either the CHIANTI database, the working directory or selected via a widget.

If set to yes, then the user is requested to enter one or more temperatures (as logarithmic values -  $\log T$ ) and correspondent column emission measures EM logarithmic values. NOTE: if more than one value is entered, then the sequence must be separated by commas (e.g.: 6.0, 6.5, 7.), and both  $\log T$  and  $\log EM$  must have the same number of values

- - Photoexcitation? If set to yes, you have to define: Trad: The blackbody radiation field temperature R/Ro: Distance from the centre of the star in stellar radius units
- - Units: Photons or Ergs
- - Protons: If set to Yes, the proton data are used to calculate the level population

Once all the parameters have been defined, the user should click on the "Calculate intensities" button to start the calculation (which calls CH\_SYNTHETIC).

Once the calculation is finished, an IDL structure is loaded into memory. It is then possible to save it for later use by clicking on the "SAVE" button.

Once the IDL structure with the line intensities is in the memory, it is then possible to calculate and plot a spectrum (SECTION 2).

#### 9.6.2 SECTION 2 - calculation of a synthetic spectrum

This section controls the parameters that are needed to fold the line intensities and the continua into a synthetic spectrum. These parameters are used by MAKE\_CHIANTI\_SPEC. Before this is done, a set of line intensities MUST be in the program memory. This is done either by calculating the intensities or by restoring a save file with previously calculated values (SECTION 1). Setting the parameters:

- -Minimum and maximum wavelengths.
- -spectrum bin size in Angstroms in Angstroms. Disallowed if an Effective area file is used.
- -instrumental FWHM: Setting this to a non-zero value broadens each of the spectral lines with a Gaussian of the specified FWHM (in Angstroms) so mimicking the effects of instrumental broadening.
- -continuum: Add continua to the binned spectrum: free-free, free-bound and two-photon. Please note that the continuum calculation takes some time and you may want to define a minimum abundance value to speed the calculations.

- - All lines? If set to no (default), only the lines for which there are observed energy levels are included. If set to yes, the "unobserved lines" will be added, but only if they are present in the structure.
- -elemental abundances: "\*.abund" files (i.e. files with a .abund extension) can be selected either from the CHIANTI database, the working directory, or via a widget.
- -select a minimum abundance value: If set not null, only the lines of those elements which have an abundance greater than the value set are selected. Also, the continuum is calculated only for those elements which have an abundance greater than the value set. This can significantly speed up the calculations. By default, the minimum value in the selected abundance file is used.
- Eff. Area: (Yes/No): If you want to fold the spectrum with an effective area. If set to Yes, you are requested to choose an input ascii file with two columns, the wavelength and the effective area values (cm²). The spectrum is multiplied with these values. the wavelenghts in the file (that might not be linear) are used to create the spectrum. Note that this option only works well if a sufficient number of bins is given. The line intensities contributing to each bin are summed, and subsequently convolved with a gaussian of full-width-half-maximum FWHM, if FWHM is not set = 0. Please note that the convolution might not work if a small number of bins is defined.

Also note that to have the correct output units (counts s-1 bin-1) the appropriately scaled DEM (or EM) values must be provided.

After this, by clicking on the "Calculate and plot" button the program calculates and plots the synthetic spectrum.

Once the spectrum is displayed, it is then possible to view the details of the lines by clicking with the mouse in the plot window, and to perform various operations by clicking on the buttons in SECTION 3

#### 9.6.3 SECTION 3 - selection of parameters for plotting and output

This Section allows the user to select a few parameters for the plotting, and to create different types of OUTPUT.

- Labels? : Setting this to yes plots a vertical line for each spectral line in the spectrum, and also writes a label above the strongest lines indicating the ion from which the line arises.
- Min.: Only lines which have an intensity greater than the value set here will be listed and, if requested, labelled and selected for inclusion in the various outputs. Setting the value=0. will result in all lines being listed and written in the outputs.
- X,Y, XOOM, UNZOOM: It si possible to select a region of the spectrum, by zooming with the use of the mouse or by setting the X,Y ranges.

NOTE that only the line details and portion of the spectrum shown will be output.

- LINEAR/LOG To plot the spectrum in linear or log scale
- Create PS file: A postscript file is created.
- Hardcopy: the postscript file "idl.ps" is created and sent to the default printer.
- Save Line details (latex): The details of the lines shown in the plot will be saved in a latex file.
- Save Line details (ascii): The details of the lines shown in the plot will be saved in an ascii file.
- Save Spectrum (ascii): The X,Y values of the spectrum are saved in an ascii file.
- Save Spectrum (IDL/FITS): The details of all the lines and the arrays of the X,Y values of the spectrum are saved into an IDL or FITS file.

Finally, SECTION 4 is a text information window, where various messages are printed. Clicking the cursor on any part of the displayed spectrum will give a listing of the lines within a range of Angtroms of that wavelength. Text information on the lines is printed.

## 9.7 Photoexcitation from any user-provided radiation field

The radiation function used in Sect. 2.2 of the v.5 CHIANTI paper for studying the O VI Doppler dimming problem is defined below.

```
FUNCTION o6_lines, lambda, a

; Vernazza & Reeves (1978) give the quiet Sun O VI 1032 flux to be
; 305.28 erg/cm2/sr/s. The 1038 line is blended with C II, so I take
; it to be half of the 1032 line. I assume the FWHMs of the lines are
; 0.2 angstroms.
;

; A Velocity (km/s) relative to emitting ions of the structure emitting
; the radiation field. A positive velocity implies a redshift.

IF n_elements(a) EQ O THEN a=0.

siz=size(lambda)
spectrum=dblarr(siz[1],siz[2])

cc=2.998d5 ; speed of light, km/s

p1=305.28/0.2
p2=p1/2.
```

c1=1031.914

```
c1=c1+ (a/cc * c1)
c2=1037.615
c2=c2+(a/cc * c2)
w=0.2/2.35
i=where(abs(lambda-c1) LE 6.*w)
IF i[0] NE -1 THEN spectrum[i]=p1*exp(-(lambda[i]-c1)^2/2./w^2)*4.*!pi/2.998d10
i=where(abs(lambda-c2) LE 6.*w)
IF i[0] NE -1 THEN spectrum[i]=spectrum[i]+p2*exp(-(lambda[i]-c2)^2/2./w^2)*4.*!
pi/2.998d10
return, spectrum
END
This function can then be used in show_pops or emiss_calc as follows:
IDL> show_pops,8,6,radfunc='o6_lines, 20',rphot=1.1
where 'o6_lines, 20' indicates that the velocity A is set to 20 km/s. A zero velocity can be
set simply by using radfunc='o6_lines'. RPHOT specifies the distance from the centre of the
star in stellar radius units.
The effects of many different velocities can be studied by doing, e.g.,
v=findgen(11)*10.
for i=0,10 do begin
  radfunc_string='o6_lines, '+trim(v[i])
  show_pops,8,6,radfunc=radfunc_string,rphot=1.1
endfor
Up to 2 input parameters are allowed for radfunc and are specified by, e.g., radfunc='radfunc,
a, b'.
Currently the RADFUNC= keyword is only available for the routines show_pops and emiss_calc.
Another example of radfunc is a blackbody
function udens_bb, lambda
t=6d3
          ; temperature of Sun, 6000 K
ee=1.439d8/lambda/t
result=8.*!pi*1.986d-8/lambda^2*(1d8^3)/lambda^3/((exp(ee)-1))
```

return, result

**END** 

which is specified to show\_pops as

```
IDL> show_pops,8,6,radfunc='udens_bb',rphot=1.1
```

The user should verify that this gives the same results as using the standard CHIANTI inputs

```
IDL> show_pops,8,6,radtemp=6000.,rphot=1.1
```

### 9.8 Non-maxwellian distribution of electron velocities

The following commands reproduce the numbers in Table 3 of the v.5 CHIANTI paper (Landi et al. 2005). Basically, we want to study the effects of non-Maxwellian distributions on two key line ratios of O VI, involving the strong lines at 1032 Å, 173 Å and 150 Å. We consider a distribution comprised of two Maxwellians at  $\log T = 5.5$  and  $\log T = 6.0$ , with the coefficients [a1,a2]=[0.75,0.25].

The effects of non-Maxwellians on level populations can be demonstrated with the show\_pops routine, e.g.,

```
IDL> show_pops,8,6,lev=-8
```

Log10 density: 10.0 Log10 temperature: 5.5

```
1
            1s2.2s 2S1/2
                           1.00e-00
2
            1s2.2p 2P1/2
                           2.30e-07
3
            1s2.2p 2P3/2
                           4.52e-07
            1s2.3s 2S1/2
                           5.07e-11
4
5
            1s2.3p 2P1/2
                           7.26e-12
6
            1s2.3p 2P3/2
                           1.44e-11
7
            1s2.3d 2D3/2
                           5.30e-12
8
            1s2.3d 2D5/2
                          7.96e-12
```

```
IDL> show_pops,8,6,lev=-8,temp=[5.5,6.0],sum_mwl_coeffs=[0.75,0.25]
```

Log10 density: 10.0

Using a sum of Maxwellians

1	1s2.2s	2S1/2	1.00e-00
2	1s2.2p	2P1/2	2.26e-07
3	1s2.2p	2P3/2	4.43e-07
4	1s2.3s	2S1/2	8.93e-11
5	1s2.3p	2P1/2	1.60e-11
6	1s2.3p	2P3/2	3.16e-11
7	1s2.3d	2D3/2	1.13e-11
8	1s2.3d	2D5/2	1.69e-11

where it can be seen that the n=3 level populations are enhanced by factors 2 by the high temperature component to the distribution.

## 9.9 Looking at level populations

To plot the populations of the first 4 levels of Si III as a function of density at a temperature of  $3 \times 10^4$  K:

IDL > plot\_populations,'si\_3',3.e+4,4

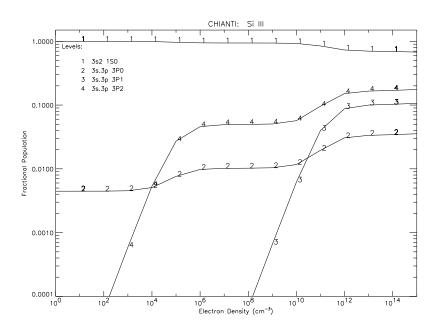

Figure 5: Output plot of PLOT\_POPULATIONS

Optionally, output files can be created.

Alternatively, SHOW\_POPS can be used. This routine has a large range of features implemented via keywords.

## 9.10 Looking at the processes that populate each level

To assess the contributions of the different physical processes to the population of a specified level within an ion, use POP\_PROCESSES.

```
IDL> pop_processes,'fe_13',lev=4
```

Level: 3s2.3p2 1D2

Log10 Temperature: 6.2 Log10 Density: 10.0

Population leaving level 4

rad. decay:	1.60e+01	42.50%
e de-exc:	3.29e-01	0.87%
e exc:	2.10e+01	55.88%
p de-exc:	2.44e-01	0.65%
p exc:	3.75e-02	0.10%
stim. emiss:	0.00e+00	0.00%
photoexc:	0.00e+00	0.00%

TOTAL 3.77e+01

101112 011110 01

Population entering level 4

rad. decay:	3.50e+01	92.98%
e de-exc:	3.38e-02	0.09%
e exc:	1.47e+00	3.92%
p de-exc:	2.81e-03	0.01%
p exc:	1.13e+00	3.01%
stim. emiss:	0.00e+00	0.00%
photoexc:	0.00e+00	0.00%

-----

TOTAL 3.77e+01

which shows that the level population is dominated by electron excitation and cascading into the level, and by radiative decay out of the level.

Note that the rates for each physical process are multiplied by the population of originating level (this results in the totals for entering and leaving the level to balance).

## 9.11 Searching for a line

If you want to list the lines within one ion around some wavelengths, you can use WHICH\_LINE. For example,

IDL> which\_line, 'o\_6', 1032

	Wavelength	i	j	Lower level	Upper level	A-value
*	1031.914	1	3	1s2.2s 2S1/2	- 1s2.2p 2P3/2	4.28e+08
	1037.615	1	2	1s2.2s 2S1/2	- 1s2.2p 2P1/2	4.21e+08

Prints a list of atomic transitions and wavelengths for lines from O VI within 1% of the input wavelength (1032 Å).

## 9.12 Looking at the different ionisation equilibria

If you are interested to see the differences between the various ionisation equilibria for e.g. Mg, you can use:

You will be able to select one of the files, and optionally create a postscript file of the plot.

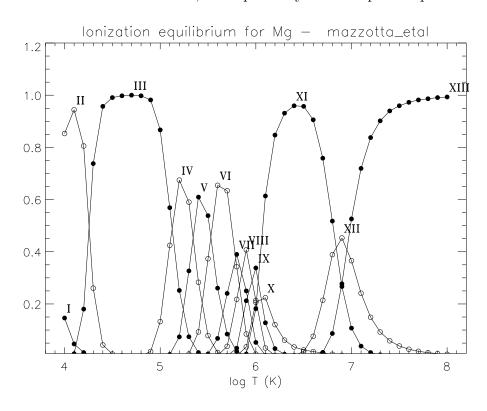

Figure 6: Output plot of PLOT\_IONEQ

If you are only interested in e.g. the Mg VIII, Mg IX, Mg X ions, you can type:

If, instead, you are interested in obtaining the temperature at the maximum ionisation fraction for e.g. Mg X, you can use:

```
IDL > print, max_temp ('Mg X')
```

You will be asked to select an ionisation equilibrium file.

## 9.13 Density and temperature diagnostics from line ratios

Spectroscopic diagnostic line ratios in the UV wavelength range have been used extensively to determine the electron density and temperature in the solar atmosphere (cf Dere and Mason, 1981, Gabriel and Mason, 1982, Mason, 1991, Mason and Monsignori Fossi, 1994). The theoretical intensity ratios from individual ion species provide a measurement of electron density which is independent of any assumptions about the volume of the emitting region. This is of particular importance in the transition region and coronal structures. The electron density (which determines the electron pressure) is an essential parameter in the study of energy transfer mechanisms. The routines that can be used are described below.

#### 9.13.1 The DENS\_PLOTTER and TEMP\_PLOTTER widgets

DENS\_PLOTTER and TEMP\_PLOTTER are high-level widgets for the analysis of densityand temperature-sensitive ratios of lines from the same ion. They allow inclusion of proton rates and photoexcitation. The calling sequence is simple:

```
IDL > dens_plotter,'o_5'
to study O V.
IDL > temp_plotter,'c_4'
```

to study C IV.

Alternatively, you can use the command-line routines, DENSITY\_RATIOS and TEMPER-ATURE\_RATIOS. They also allow inclusion of proton rates and photoexcitation via KEY-WORDS.

#### 9.13.2 The DENSITY\_RATIOS procedure

The routine DENSITY\_RATIOS plots the variation of line intensities with electron density, allowing density diagnostics to be studied. As an example, we can look for density sensitive line ratios of O V in the 1000 to 1500 Å wavelength region for densities between  $10^8$  and  $10^{13}$  cm<sup>-3</sup>:

```
IDL > density_ratios, 'o_5', 1000., 1500., 8., 13., den, rat, desc
```

two windows will open and plot the relative intensities of a few O V lines. To choose the ratio of 1371.294 to 1218.393 Å line, select first the 1371.294 Å line. Another widget will appear to select the denominator. Select the 1218.393 Å line. This will chose the ratio of 1371.294 to 1218.393 which will be plotted in a new window. Values of the density and intensity ratio will be put into the variables den and rat and desc will contain a descriptive string.

```
IDL > print, desc IDL > CHIANTI V. 4.0 0 V 1371.2939 ()/1218.3929 () T = 2.51e+05 (K)
```

The DENSITY\_RATIOS procedure also allows to calculate the ratio at user-defined value of constant temperature. Blends are accounted for via a selection of lines.

#### 9.13.3 The TEMPERATURE\_RATIOS procedure

To calculate temperature sensitive line ratios of C IV for lines between 100 and 1600 Å for temperatures between  $10^4$  and  $10^6$  K:

```
IDL > temperature_ratios,'c_4',100.,1600.,4.,6.,temp,rat,desc
```

As with density\_ratios, a widget will appear that will allow you to select the numerator. Select the 384.175 and 384.190 Å lines as these will typically be blended in most spectrographs. Select the 1550.775 Å line for the denominator. The ratio of (384.175 + 384.190 Å) to the 1550.775 Å line as a function of temperature will be plotted and stored in the variables rat and temp, respectively. The TEMPERATURE\_RATIOS procedure also allows to calculate the ratio at user-defined values of either constant pressure or constant density.

```
IDL > print, desc
IDL > CHIANTI V. 4.0 C IV 384.1750+384.1900 ()/1550.7750 () Ne = 1.00e+10 (cm!e-3!n)
```

#### 9.13.4 The CHIANTI\_NE and CHIANTI\_TE widgets

The IDL procedure which calculates line intensity ratios as a function of electron density is called CHIANTI\_NE. Another IDL procedure to calculate ratios sensitive to electron temperature is called CHIANTI\_TE. For example,

```
IDL > chianti_te
```

Or

```
IDL > chianti_ne
```

User interactions with the main widget setup the wavelength range and other parameters that are described individually below. On the left hand side are controls for wavelength and electron density or temperature selection and on the right hand side for ion selection.

#### Ion selection

Select first the element and then the ion stage using the pull-down menus. Only those elements and ions currently available in the CHIANTI database are displayed for selection.

#### Wavelength ranges

There are up to 4 wavelength ranges that can be defined in order to restrict the calculation (and the number of lines). At least one should be defined. Default is to calculate all lines from 1 to 1700 Å.

#### Electron Density/Temperature Range

For CHIANTI\_NE, select the electron number density range (Log<sub>10</sub> $N_e$ ) over which the intensity ratios are calculated. Default values are  $10^6$  to  $10^{14}$  cm<sup>-3</sup>. The intensity ratios are calculated at constant temperature corresponding to the peak ionic abundance  $T_{max}$ , unless the value of the temperature is typed in.

For CHIANTI\_TE, select the electron temperature ( $Log_{10}T_e$ ) over which the intensity ratios are calculated. Default values are  $10^4$  to  $10^8$  K. The intensity ratios are calculated at a constant electron number density corresponding to  $10^8$  cm<sup>-3</sup>, unless a different value is typed in.

#### minimum intensity ratio

The relative intensity of all the lines found in the wavelength range is calculated. Only the lines that have an intensity (relative to the brighter one) greater than 0.0001 (by default) are selected and displayed.

#### Units for the ratio plot

The ratios can either be calulated from the relative intensities in ergs (default) or photons.

#### Controlling the procedure

The action of both CHIANTI\_NE and CHIANTI\_TE is controlled via the buttons in the central panel of the display. From left to right these are:

QUIT - click on this to exit from the program, all plot windows are also deleted.

CALCULATE LINE INTENSITIES - using the wavelength ranges as defined in the widgets above. Two plots will apear in the window - on the left the  $N_i * A/N_e$  and on the right the intensity ratios, where  $N_i$  is the level population and A is the radiative transition probability  $(s^{-1})$ . A list of spectral lines in the given wavelength range for that ion is displayed in the message window. The reference index is in the first column, then the wavelength, intensity and transition.

PLOT RATIO - prompts for and then plots specific line intensity ratios, using line indices available from the list. The ratios within a particular ion can be stored for later use using the SAVE button. To allow for blended lines in the observed spectra, multiple line indices can be given for the numerator and denominator. The format is fairly flexible but the nominator and denominator specification must be separated by a '/'. Otherwise the line indices can be separated by spaces or commas. The ratio values can be plotted either with a linear or a log scale.

HARDCOPY - the menu under this button will allow a variety of hardcopy plots (ratio plots or intensity plots) and the line details (+refs), which gives a record of the input. A line ratio has to be defined.

SAVE - it is sometimes useful to save the plotted line intensity ratios to study several different ions. You will be asked to enter file name to store ratio data. A line ratio has to be defined. In the CHIANTI\_NE case, a .CH\_NE will be appended. An IDL structure called NE\_RATIO will be saved. It has the TAGS: DENSITY,RATIO, TEMPERATURE, UNITS, COM-

MENT, DESC. The first two have the arrays of the densities and ratios, TEMPERATURE has the value of the constant temperature used, while the last three have a description of the units used, how the calculation was performed, and a description of the lines used to defined the ratio.

In the CHIANTI\_TE case, a .CH\_TE will be appended. An IDL structure called TE\_RATIO will be saved. It has the TAGS: TEMP, RATIO, DENSITY, UNITS, COMMENT, DESC. The first two have the arrays of the temperatures and ratios, DENSITY has the value of the constant density used, while the last three have a description of the units used, how the calculation was performed, and a description of the lines used to defined the ratio.

Please note that previous versions of the above routines did not create the TEMPERATURE (DENSITY), UNITS, COMMENT tags.

The save file can be restored and replotted outside of CHIANTI\_NE and CHIANTI\_TE using the procedures PLOT\_CHIANTI\_NE and PLOT\_CHIANTI\_TE respectively, or used within user-defined procedures.

DELETE PLOT WINDOWS - to clear the ratio plots from the screen.

#### 9.13.5 The PLOT\_CHIANTI\_NE and PLOT\_CHIANTI\_TE procedures

The ratio values stored in the save files created with the CHIANTI\_NE and CHIANTI\_TE routines can be replotted outside of CHIANTI\_NE and CHIANTI\_TE using the procedures PLOT\_CHIANTI\_NE and PLOT\_CHIANTI\_TE respectively. For example,

```
IDL > plot_chianti_te
```

Or

IDL > plot\_chianti\_ne

If no files are specified, a widget allows you to select any '\*.CH\_NE' or '\*.CH\_TE' files. A LOG keyword allows the user to have the plot in a log scale.

It is also now possible to interactively modify the X and Y ranges and to create a postscript file. Users can modify these routines to e.g. over-plot observed data points.

#### 9.13.6 Calculating temperatures by using different ions

Note: If you are interested in **determining an isothermal temperature by using the** ratio of lines emitted by different ions (and/or elements), then a possible way is to first calculate the contribution functions of the lines you are interested, and then calculate their ratio. Note, however, that such determinations can be very inaccurate, since they depend on the ionisation equilibrium chosen (and eventually on the element abundance).

## 9.14 Calculating contribution functions

To calculate the contribution function ( $erg \ cm^3 s^{-1} sr^{-1}$  by default) vs. temperature at a specified abundance, ionization equilibrium and pressure or density for the Fe XXIV line at 255.1 Å:

temperature, g are the arrays with the temperatures and the G(T) values. It is possible to calculate the G(T) at either constant electron density or pressure, via the KEYWORDS DENSITY or PRESSURE.

The KEYWORDS ABUND\_NAME, IONEQ\_NAME allow to run the routine in the background, giving names of the abundance and ionization fractions files.

The routine GOFNT allows the user to select a number of lines. If this is done, then the total sum of the G(T)'s of the selected lines is returned and plotted.

Optional outputs can be created. The default units are  $erg\ cm^3s^{-1}sr^{-1}$ , unless the KEY-WORD /PHOTONS is set, in which case the units are photons  $cm^3s^{-1}sr^{-1}$ .

## 9.15 Calculating radiative losses

A procedure ('RAD\_LOSS') calculates the total radiative loss rate as a function of temperature for specified set of abundances and/or ionization equilibria:

#### IDL > rad\_loss,temperature,loss\_rate

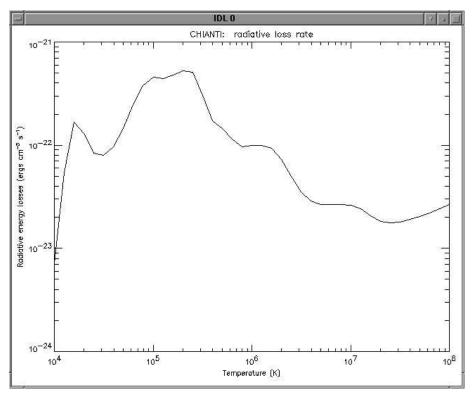

Figure 7: Output plot of RAD\_LOSS

#### 9.16 The calculation of the DEM

Given a set of observed spectral intensities, the problem is to invert a system of integral equations like the previous one. The procedure CHIANTI\_DEM solves the system and calculates the DEM(T).

The inversion problem itself is not simple and requires some assumptions about the nature of the solution. A series of workshops was sponsored in 1990/91 to study differential emission measure techniques (Harrison and Thompson, 1992). It was found that most codes eventually gave consistent results, but that the DEM derived depends rather critically on the methods used to constrain the solution and the errors in the observed intensities and atomic data.

It is advisable to select a number of well resolved, unblended lines which are not density sensitive, emitted by various elements over a wide temperature interval. Appropriate values of the pressure (or density) and the elemental abundances must be chosen according to the region of the Sun being observed. The pressure value can be obtained once the values of the temperature and the density are estimated. To estimate the electron density the procedure CHIANTI\_NE can be used. The temperature can be estimated for example using the procedure CHIANTI\_TE.

The contribution functions  $C(T, \lambda_{ij}, N_e)$  can be calculated using CHIANTI\_DEM either at constant pressure or at constant electron density. It is also possible to vary the elemental abundances before starting the fit to deduce the DEM.

Many papers have been written on solar elemental abundances. See e.g. Meyer (1993) Widing and Feldman (1992), Mason (1992, 1995). A possible approach in determining elemental abundances is to use the detailed shape of the DEM distribution for ions from the same element and apply an iterative procedure to normalize the curves for different elements (e.g. Fludra and Shmelz 1995, Del Zanna et al. 1995).

#### The CHIANTI\_DEM procedure

The main IDL routine which has been written to perform a differential emission measure analysis of EUV spectra using the CHIANTI atomic database is CHIANTI\_DEM. Other procedures required to run CHIANTI\_DEM are GET\_CONTRIBUTIONS, DEM\_FIT, ZION2SPECTROSCOPIC and Z2ELEMENT. The resulting DEM may then be used by other procedures to calculate a synthetic spectrum.

This package of routines will be replaced in the future by new more versatile versions. The main inputs required by CHIANTI\_DEM are :

- the file with the observed fluxes. It can be selected using a widget-type browse from within CHIANTI\_DEM or using the optional keyword FILE\_INPUT='myfilename'. It must contain 5 columns of unformatted data ( separated by at least one space). The 5 fields are:
  - 1) the observed wavelength  $\lambda_{obs}$  [Å].
  - 2) The observed flux  $I_{obs}$  in  $ergs\ cm^{-2}s^{-1}sr^{-1}$ .
  - 3) The corresponding error  $\sigma_{obs}$  on the flux in  $ergs~cm^{-2}s^{-1}sr^{-1}$ .
  - 4) The value of  $\delta\lambda$  [Å]. All the theoretical lines that may have contributed to the observed lines, i.e. that have a theoretical wavelength  $\lambda_{theo}$  in a  $\lambda_{obs} \pm \delta\lambda$  range will be

searched for. This value should correspond to the spectral resolution of the instrument at that wavelength.

5) The identification, written as a string of up to 20 characters. For example:

171.114 4811.0 1443.0 0.25 Fe IX

174.604 4005.0 1202.0 0.25 Fe X

180.448 3877.0 1163.0 0.25 Fe XI bl Fe X

195.149 3443.0 1033.0 0.25 Fe XII

- the pressure  $N_eT$  [ $cm^{-3}K$ ] or the density  $N_e$  [ $cm^{-3}$ ], passed to the routine via a keyword.
- the ionization equilibrium file, selected using a widget.
- the elemental abundances file. A selection of files are already stored in the CHI-ANTI package, but user-defined files in the working directory can also be used. Any \*.abund file present in the CHIANTI database or in the working directory can be selected through a widget from within CHIANTI\_DEM. The selected file can also be edited.
- An output file name must also be supplied via a keyword (e.g. OUTPUT= 'active\_region'). Various files will be generated by CHIANTI\_DEM having file names created by adding suffixes to the output file name.

Once the file with the observed fluxes is read, another IDL procedure, GET\_CONTRIBUTIONS, is called by CHIANTI\_DEM in order to calculate the contribution functions  $C(T, \lambda_{ij}, N_e)$  at the given constant density or pressure.

GET\_CONTRIBUTIONS searches the CHIANTI database for all the theoretical lines that may have contributed to the observed lines, i.e. that have a theoretical wavelength  $\lambda_{theo}$  in a  $\lambda_{obs} \pm \delta \lambda$  interval.

Then, for each theoretical line selected, it calculates the C values for the temperature interval  $\log(T) = 4.0 - 8.0$  in steps of  $\log(T) = 0.1$ .

If a constant pressure is selected, for each ion the contribution function is calculated at an electron density  $N_e$  equal to the ratio of the pressure and the temperature of maximum ionization fraction.

The C(T) values are stored by GET\_CONTRIBUTIONS in the output file *output.contributions* that can be used later, if required, to re-calculate the DEM, changing various parameters (e.g. the abundances), without having to start again and read the CHIANTI database, which can take a long time.

The observed lines with no theoretical counterparts are automatically excluded. If this happens, you might consider starting again with a larger  $\delta\lambda$ , to see if there are theoretical lines in the vicinity of the observed one.

Then you are asked to select an \*.abund file present in the CHIANTI database or in the working directory, and eventually edit it, if you want to change some abundances.

The G(T) are calculated, multiplying each theoretical line by the abundance factor. The theoretical lines contributing to each blend are sorted by intensity and then their G(T) can

be plotted if the keyword PLOT\_GT was activated. It is recommended to do this the first time, to check if there are some observed lines which are heavily blended with lines of other elements. It might be better to exclude such lines in a second run.

The G(T) for each blend are then summed and plotted, and the calculation of the DEM starts, using the fitting routine DEM\_FIT. A series of parameters can change the result (DEM), especially the number and position of the mesh points of the spline that represents the DEM. The fitting procedure is based on Bevington's Data Reduction and Error Analysis for the Physical Sciences. fortran programs.

The iteration is controlled using key-words (see below).

A series of outputs are created, all having extensions of the output name. For example, using test as the output name:

- test.contributions: The first three lines contain the abundance file, the ionization equilibrium file names, and the constant value of the pressure or the density adopted. Each subsequent line contains the observed wavelength  $\lambda_{obs}$ , the theoretical one  $\lambda_{theo}$ , the element and ionization stage, the C(T) values and the specification of the transition.
- test.dem: Is the file where the DEM(T) values are written, in a format suitable for input to the CHIANTI\_SS procedure which may be used to calculate a synthetic spectrum from the DEM.
- test.general: Is the file where general information is stored.

The abundance file, the ionization equilibrium file and the pressure used are written at the beginning.

Then there is one line for each observed line, with the identification present in the input file, the observed wavelength  $\lambda_{obs}$ , the observed flux  $I_{obs}$ , the calculated flux  $I_{theo}$ , the error on the flux  $\sigma_{obs}$ , the value  $(\frac{I_{theo}-I_{obs}}{\sigma_{obs}})^2$  and finally the value of  $\frac{I_{theo}}{I_{obs}}$ 

After this line, there is one line for each theoretical line contributing to the blend, with the identification, the theoretical wavelength  $\lambda_{theo}$ , the configuration and terms, and the contribution (as a percentage) of each line in the blend to  $I_{theo}$ .

- test.out: This file, toghether with test.dem, can be used to reproduce the results using user-written software. It contains: the identification present in the input file, the observed wavelength  $\lambda_{obs}$ , the observed flux  $I_{obs}$ , the calculated one  $I_{theo}$ , the error on the flux  $\sigma_{obs}$ , and the logarithmic values of the temperature and the DEM for each observed line. This temperature is the value where the product G(T) \* DEM(T) has a maximum.
- three optional postscript files:  $test\_gt.ps$   $test\_dem.ps$   $test\_4plots.ps$ .

The first one has the G(T) of all the lines then used for the fit, with all the contributions for each line summed (the labels refer to the identification given in the input file).

The file  $test\_dem.ps$  has the DEM(T) with the scales set as in the interactive session. The points are plotted at the temperature where the product G(T)\*DEM(T) has a maximum. It is possible to label the points with the comment string present in the input file, or to use the dominant ion in the blend.

The file  $test\_4plots.ps$  has some additional plots. The upper-right figure of  $test\_4plots.ps$  plots the values  $\frac{I_{theo}}{I_{obs}}$  versus the temperature where G(T) has it's maximum.

• It is also possible to have postscript files of the G(T) functions, using the keyword PLOT\_GT.

#### 9.16.1 Controlling the procedure

The action of CHIANTI\_DEM is controlled via the following keywords.

where all the contribution functions C(T) are stored.

the density must be set in this case.

- FILE\_INPUT: optional; if not set, you are prompted to select the observation file using a widget-type search.
- ARCSEC: optional set this if the intensities are specified in units per  $arcsec^{-2}$ . The default units are ergs  $cm^{-2}s^{-1}sr^{-1}$ .
- PHOT: optional; set this if the intensities are specified in units per steradians<sup>-1</sup>. The default units are ergs  $cm^{-2}s^{-1}sr^{-1}$ .
- OUTPUT : required; the name for the output. Suffixes will be added to this name when creating the various outputs.
- FILE\_GT: if **not** set, the routine GET\_CONTRIBUTIONS is called. **Either** the pressure or the density must be set in this case.

  If set, it has to specify the name of the file previously created by GET\_CONTRIBUTIONS,
- PRESSURE: the value of the pressure (Ne T). Required if you do **not** already have the contribution functions C(T) (i.e. if you **do not** set FILE\_GT). **Either** the pressure or
- DENSITY: the value of the electron density (Ne). Required if you do NOT already have the contribution functions C(T). **Either** the pressure or the density must be set in this case.
- CUT\_GT: optional; if set, only those theoretical lines that have a MAX(C(T)) greater than the value set, are kept; it is useful to set this value in order to reduce the number of lines in the file where the C(T) are stored. If not set, a default value of  $10^{-30}$  is adopted.
- N\_MATCHES: optional; in the unlikely event that more than 20 (default value for N\_MATCHES) theoretical lines corresponding to an observed line are found, the routine stops. In this case, you have to start again setting N\_MATCHES equal to a greater number.
- PLOT\_GT: optional; if set, plots of the G(T) of the theoretical lines contributing to each observed line not excluded are created. It is possible to change the scale and create postscript files of these plots, interactively.

- EXCLUDE\_OBS\_WVL: optional; if set, has to be an array that specifies the wavelengths of the lines that you want to exclude from the fit. Note that even if you set this keyword and run GET\_CONTRIBUTIONS all the theoretical lines found corresponding to all the lines in the input file are written in the C(T) file. It is only in the fit that the lines are excluded.
- MESH\_POINTS: optional; it is an array that specifies the mesh points for the spline that represent the fitted DEM, in log(T). If not set, the default values [4,4.5,5,5.5,6,6.5,7,7.5,8] are assumed.
- N\_ITER: optional; it is the maximum number of iterations of the fitting routine. If not set, a default value of 20 is assumed. Changing this value alone might not affect the fit, since the value of DCHISQ\_M is monitored at each iteration to check for convergence.
- DCHISQ\_M: optional; if not set, a default value of DCHISQ\_M=  $1 \cdot 10^{-5}$  is assumed. For each iteration, the  $\chi^2$  and it's variation are calculated. As long as the iteration achieves a relative improvement in  $\chi^2$  greater than DCHISQ\_M, another iteration will be performed.
- DEM\_FILE: optional; if set you are prompted to choose a DEM file to be used initially, instead of the default constant value of 10<sup>22</sup>. You can either choose one of the files in the CHIANTI database or any you have in the working directory. A plot of the DEM is created. The values in the file are marked as crosses, the mesh points are marked with triangles.
- QUIET: optional. Set to avoid various messages and the details of the result.

There are also some actions controlled via the keyboard.

When you are asked for an answer ([y/N]) yes or no you should either type in y or n. The capital letter in [y/N] means that the default choice is n which is what you get if you simply hit the **return key**. In case you have [Y/n], hitting the **return key** is the same as choosing y.

#### 9.16.2 Examples

You must specify the output file name and the value of the pressure (or the density). The input file name is optional.

IDL > CHIANTI\_DEM,OUTPUT='test',FILE\_INPUT='test\_obs',PRESSURE=1e16,/PLOT\_GT

Select the ionization equilibrium file (e.g. Arnaud & Raymond). If there are no problems about N\_MATCHES, the routine will select the lines having  $max(C(T)) \ge 10^{-30}$  and write the C(T) values to the file test.contributions.

Then you'll be asked to select an abundance file and if you want to edit it. Pick up the Feldman abundances. Then the G(T) are calculated, multiplying each theoretical line by the abundance factor, sorted (within each blend) by their  $\max(G(T))$  value, and plotted (see Fig. 8).

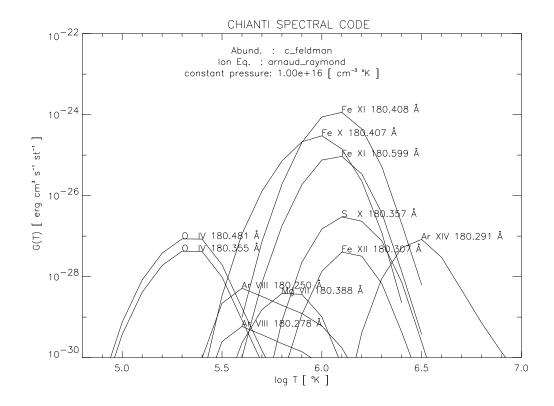

Figure 8: One of the G(T) plot of the test case

It is recommended that you check the plots at least once, to see if there are some observed lines that it might be better to exclude in a second run, for example because they are blends. Also check if your identifications are consistent with the lines found in the CHIANTI database.

The G(T) for each blend are then summed, and plotted (see Fig. 9).

At the end of the fit, the files test.dem, test.general, test.out are created.

Have a close look at these outputs, and check if there are emission lines not well represented by the fit or with no theoretical counterparts.

You can use the routine a second time, excluding some of the lines, and/or varying some of the fitting parameters. In particular, changing MESH\_POINTS or starting from an appropriate DEM can affect the resulting DEM. For example:

```
IDL> CHIANTI_DEM,OUT='test',FILE_IN='test_obs',FILE_GT='test.contributions', $
IDL> EXCLUDE_OBS_WVL=[ 284.153 ] ,$
IDL > MESH_POINTS= [ 4.85, 5.6, 6.25, 7.0 ],N_ITER=40
```

The files test.dem, test.general, test.out will be created.

Eventually, also the files test\_dem.ps test\_4plots.ps may be created.

Fig. 10 shows the resulting DEM. The error bars on the points simply reproduce the error on the observed fluxes.

The Fig. 11 is self-explanatory. The DEM figure is repeated in the upper-left plot with the same scale of the previous plot.

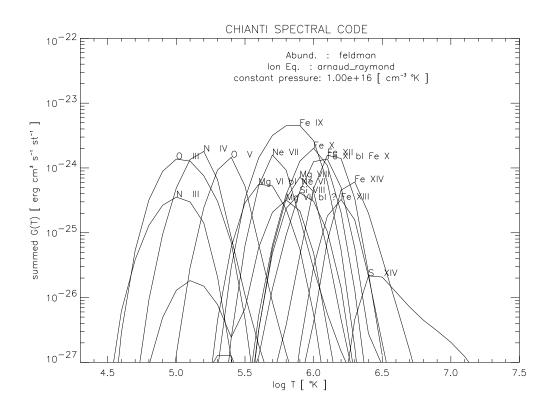

Figure 9: The summed-G(T) plot of the test case: test\_gt.ps

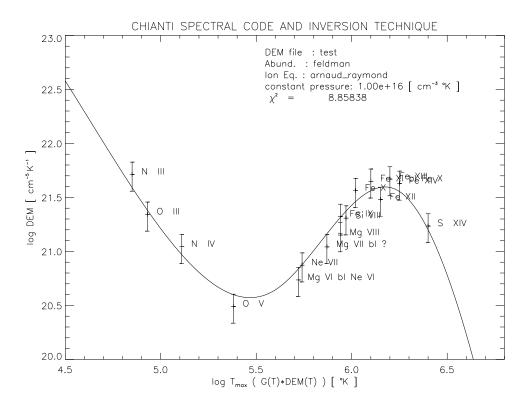

Figure 10: The DEM plot of the test case: test\_dem.ps

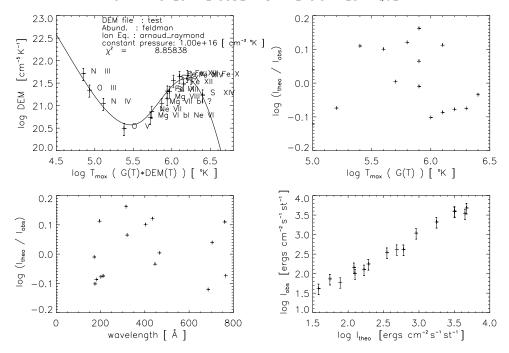

Figure 11: The 4 plots of the test case: test\_4plots.ps

The file *test.out*, toghether with *test.dem*, can be used to reproduce these plots using user-written software. If the only concern is the postscript output, then users just have to copy the routine in the working area and modify the top procedure PRINT2D\_PLOT.PRO that controls the postscript device. The default is landscape.

#### 9.16.3 Some final remarks

This package is mostly intended to be a quick method to obtain a DEM which can then be used to calculate a synthetic spectrum, to be compared with the observed data.

Try to give as input lines covering a broad range in temperatures, and that are not density sensitive.

Try to adjust the location of the mesh points.

If the resulting DEM does not give a good fit to the data, it might be a good idea to start again calculating the G(T) with different abundances or to check the effect of blends.

Try a different DEM as a starting point, but be careful about the end points at lower and higher temperatures where usually there are no constraints (no observed lines).

Consider the possible effect on the DEM of different structures along the line of sight. It is important to realise that the DEM gives an indication of the amount of plasma at different temperatures along the line of sight, assuming constant density or pressure. It is not therefore possible to infer direct information about the variation of the temperature with height from this function. The inclusion of density-sensitive lines in the fit may also cause problems.

# A Description of the CHIANTI V.4 software updates

## A.1 Routines already available in Version 3

The previous routines have been modified as described:

• ascii\_wvl\_dem.pro creates an ascii file with a list of line identifications and intensities.

Compared to the previous version, these are the main changes:

- 1-Rewritten as a wrapper routine using the new procedures.
- 2-Now the PRESSURE value is a keyword.
- 3-The calculations can be done at constant DENSITY.
- 4-Energies (keV) can be output instead of wavelengths in Angstroms
- 5-MASTERLIST can now be used both as an input string or as a keyword.
- latex\_wvl\_dem.pro creates a latex file with a list of line identifications and intensities.

Compared to the previous version, these are the main changes:

- 1-Rewritten as a wrapper routine using the new procedures.
- 2-Now the PRESSURE value is a keyword.
- 3-The calculations can be done at constant DENSITY.
- 4-MASTERLIST can now be used both as an input string or as a keyword.
- synthetic.pro Calculates a synthetic spectrum. It outputs arrays.

Compared to the previous SYNTHETIC, these are the main changes:

- 1-Rewritten as a wrapper routine using the new procedures.
- 2-Now the PRESSURE value is a keyword as the DENSITY value
- 3-The keyword CONT is now renamed CONTINUUM
- 4-Added keywords

```
PHOTONS (If set, intensities are in photons instead of ergs)
```

DEM\_NAME, ABUND\_NAME, IONEQ\_NAME, to run the routine in the background, giving names of the DEM, abundance and ionization fractions files.

NOPROT (If set, then proton rates are not included.)

RADTEMP, RPHOT (to include photoexcitation)

- 5-MASTERLIST can now be used both as an input string or as a keyword. 6-The description of the line details now has the spectroscopic designation at the end.
- synthetic\_plot.pro plots the spectrum and interactively identify lines Is left unchanged except for a few minor changes.
- gofnt.pro calculates the contribution functions

  Aside from a few small fixes, these are the main changes:

  1-Rewritten as a wrapper routine using the new procedures.
  - 2-Added keywords

ABUND\_NAME, IONEQ\_NAME, to run the routine in the background, giving names of the abundance and ionization fractions files.

NOPROT (If set, then proton rates are not included.)
RADTEMP, RPHOT (to include photoexcitation)

- isothermal.pro Calculates line intensities with an isothermal approximation. Compared to the previous routine, these are the main changes:
  - 1-Rewritten as a wrapper routine using the new procedures.
  - 2-Added keywords

ABUND\_NAME, IONEQ\_NAME, to run the routine in the background, giving names of the abundance and ionization fractions files.

NOPROT (If set, then proton rates are not included.)

RADTEMP, RPHOT (to include photoexcitation)

EM Emission measure values.

• chianti\_ss.pro Widget for creation of SOHO synthetic spectra.

Is not distributed nor supported anymore. Is now replaced by ch\_ss.pro

• plot\_populations plots the level populations

Compared to the previous routine, these are the main changes:

1-Modified the plotting, adding information about the single lines.

2-Added keywords

```
NOPROT (If set, then proton rates are not included.)

RADTEMP, RPHOT (to include photoexcitation)
```

• density\_ratios plots the variation of line intensities with electron density Compared to the previous routine, these are the main changes:

1-Rewritten as a wrapper.

2-Added keywords

```
NOPROT (If set, then proton rates are not included.)
RADTEMP, RPHOT (to include photoexcitation)
```

• temperature\_ratios plots the variation of line intensities with electron temperature 2-Added keywords

```
PHOTONS (If set, intensities are in photons instead of ergs)

IONEQ_NAME The ionization fractions file.

NOPROT (If set, then proton rates are not included.)

RADTEMP, RPHOT (to include photoexcitation)
```

• freefree calculates the free-free (bremsstrahlung) continuum

The call is the same, but the calculations are done using the fitting formulae of Itoh et al. (ApJS 128, 125, 2000) and Sutherland (MNRAS 300, 321, 1998). Also, a few bugs have been fixed.

- freebound.pro calculates the free-bound continuum
   Added the keyword
   PHOTONS (If set, intensities are in photons instead of ergs)
- rad\_loss.pro calculates the radiative losses
  -Added keywords

```
NOPROT (If set, then proton rates are not included.)
RADTEMP, RPHOT (to include photoexcitation)
```

# A.2 Other routines that were previously available only within SolarSoft

These routines are in the other/ subdirectory:

- max\_temp.pro Calculates temperature at max ionisation ratio for an ion Unchanged.
- plot\_ioneq.pro Plots the ionisation equilibrium values for an element. Unchanged.
- chianti\_ne.pro Calculate and plot density sensitive line ratios.

  Widget unchanged but the low-level routine now uses emiss\_calc.pro.
- plot\_chianti\_ne.pro Plots a density sensitive ratio saved from CHIANTI\_NE Unchanged.
- chianti\_te.pro Calculate and plot temperature sensitive line ratios.

  Widget unchanged but the low-level routine now uses emiss\_calc.pro.
- plot\_chianti\_te.pro Plots a temperature sensitive ratio saved from CHIANTI\_TE Unchanged.
- chianti\_dem.pro Calculates the Differential Emission Measure DEM(T) using the CHIANTI database, from a given set of observed lines.
  - Changed the low-level routine that calculates the G(T), to account for the v.4 variations. The proton rates are included in the calculation of the level population.
- plot\_dem.pro To plot differential emission measure (DEM) values
   Unchanged.

Routines in the extra/ subdirectory:

- dens\_plotter.pro A widget routine to allow the analysis of density sensitive ratios.

  Is now a wrapper routine calling the widget RATIO\_PLOTTER
- temp\_plotter.pro A widget routine to allow the analysis of temperature sensitive ratios.

Is now a wrapper routine calling the widget RATIO\_PLOTTER

- g\_of\_t.pro To compute the G(T) of selected lines.
   A few keywords have been added/ modified, mainly as an update for V.4.
- pop\_plot.pro To plot  $n_j A_j i/N_e$  values as a function of  $N_e$ A few keywords have been added/ modified, mainly as an update for V.4.
- show\_pops.pro To display populations of significant levels in a CHIANTI ion model A few keywords have been added/ modified, mainly as an update for V.4.
- emiss\_calc.pro To compute the emissivities of all lines of a specified ion over given ranges of temperature and density.
  - A few keywords have been added/modified, mainly as an update for V.4.
- integral\_calc.pro To compute the atomic data integral for use in column or volume emission measure work.

A few keywords have been added/ modified, mainly as an update for V.4.

# B Incorporating proton rates into CHIANTI

This section describes the changes applied to the CHIANTI database and software in order to include the proton rates.

## B.1 The proton rate data files

The proton rate data files have suffices .psplups and have the following format

```
2 3 2 0.000e+00 1.027e-02 8.000e+02-2.150e-13 1.052e-13 4.397e-12 \ 2.232e-11 5.389e-11 8.708e-11 1.014e-10 7.658e-11-2.805e-12
```

(The \ indicates a break in the line.) Note that the Z and spectroscopic number are not given for each ion, in contrast to the electron files. The rest of the line is the same as that for the electron files, except in this case there are 9 spline values as a 9-point spline was fitted to the data.

# B.2 Reading the .psplups file

This is done by the routine read\_splups.pro which loads the data into an IDL structure. The call is

```
IDL> read_splups_ns, filename, splstr, splref , /prot
```

The structure splstr has the following tags

```
.lvl1 lower level index
.lvl2 upper level index
.t_type transition type
.gf    gf value
.de    Delta-E for transition (rydbergs)
.c_ups    the scaling parameter
.nspl    number of spline points
.spl    Vector of length 9, containing spline points
```

## B.3 Changes to pop\_solver.pro

The routine pop\_solver solves the set of linear equations that determine the level balance of the ion. To include proton rates, an extra matrix containing the proton rate coefficients needs to be added to the equations. This matrix is created within pop\_solver from the splstr structure mentioned above.

Note also that the same routine is used to descale the spline fits into proton rates as to descale the electron spline fits. This routine is descale\_all.pro and is called as

```
descale_all, temp, splstr, index, ups
```

where temp can be an array of temperatures.

# B.4 Implementing proton rates in user-written routines

User-written routines can be modified to include proton rates through two steps.

For routines which *do not* directly call pop\_solver, the only changes are to add the keywords noprot=noprot, abund\_file and ioneq\_file to the routines' argument list, and to the call to the routine that calls pop\_solver.

For routines that directly call pop\_solver, the following steps need to be followed.

The first is to add the keyword noprot=noprot to the routine's argument list.

The second is to add a common block analogous to those that already exist for the energy level, radiative and electron collision data. This common block is

```
COMMON proton, pstr, pe_ratio
```

The third step is to add a line which will read the data. This is

```
if keyword_set(noprot) then begin
   pstr=-1
endif else begin
   read_splups, pname, pstr, pref, /prot
endelse
```

Before the call to pop\_solver, the proton to electron ratio must be evaluated. This is done with

```
pe_ratio=proton_dens(temp)
```

where temp contains the logarithm of the temperatures that will be passed to pop\_solver.

## B.5 The proton-to-electron ratio

To include the proton rates in CHIANTI it is necessary to know the proton number density  $N_{\rm p}$ . This quantity is usually expressed in terms of the ratio relative to the electron density. For a standard solar plasma this is a constant for temperatures beyond  $\log T = 4.6$  with a value around 0.85. Thus one option is to simply fix the ratio as a constant.

As we want CHIANTI to be applicable for low temperature plasmas, however, we have decided to explicitly calculate the ratio making use of the ion balance and abundance files, that uniquely determine  $N_{\rm p}$ . The relevant routine is PROTON\_DENS.PRO.  $N_{\rm p}$  is calculated from the ion balance and element abundance files contained in CHIANTI through the following expression

$$R(T) = \frac{N_{\rm p}}{N_{\rm e}} = \frac{\text{Ab(H)}F(\text{H}^+, T)}{\sum_{i=1}^n \sum_{z=1}^i ZF(\text{A}_i^{+Z}, T)\text{Ab(A}_i)}$$
(37)

where Ab is the element abundance,  $A_i$  is the *i*th element (i.e.,  $A_1$ =H,  $A_2$ =He, etc.), Z is the charge on the ion,  $F(A_i^{+Z}, T)$  is the fraction of ions of element  $A_i$  in the form  $A_i^{+Z}$  at temperature T.

The ion fractions contained in CHIANTI are tabulated over the range  $4.0 \le \log T \le 8.0$ . Above and below these values, we set R(T) to the values for  $\log T = 8.0$  and  $\log T = 4.0$ , respectively.

The use of this routine has some side effects. Some routines for which the ratio may have some effects in the results don't require you to select the ion balance or abundance files. E.g., DENSITY\_RATIOS.PRO does not require the user to select these files, however, at low temperatures one may see significant changes take place in line ratios on account of the change in the proton-to-electron ratio. We deal with this effect by using the default <code>!abund\\_file</code> and <code>!ioneq\\_file</code> files to derive the proton-to-electron ratio, but allowing the files to be directly specified by the user through keywords if he/she needs to do this.

### B.5.1 Implementing proton rates in user-defined procedures

We have modified the CHIANTI routines so as PROTON\_DENS.PRO is called once at the beginning of the routine and the ratio data are passed to POP\_SOLVER.PRO through a common block.

The modifications due to the proton-to-electron ratio in user-defined procedures are as follows:

• Extend the PROTON common block to include ratio data.

```
common proton, pstr, pe_ratio
```

• If the ELEMENTS common block does not already exist in the routine, then it must be added

```
COMMON elements, abund, abund_ref, ioneq, ioneq_t, ioneq_ref
```

• Call PROTON\_DENS.PRO to get the ratio

```
pe_ratio=proton_dens(temp)
```

The call to PROTON\_DENS.PRO thus does not take place within POP\_SOLVER.PRO

# C Incorporating 9 point spline fits into user-defined procedures

This section describes the changes in the IDL software required to incorporate the 9-point spline fits.

## C.1 Data file format changes

The modification to the .splups file is simple. Any transitions which are fitted with a 9-point spline will simply have four extra numbers placed on the end of the data line. Transitions fitted with a 5-point spline will be output as normal. Both 5 and 9-point fits can be found in the same .splups file.

## C.2 Changes to existing software

This section describes the changes to the read\_splups routine, and also the changes required to routines that call directly or indirectly read\_splups.

For some routines (such as synthetic, ...?) the reading of the data files is delegated to the routine setup\_ion.pro. The data is then transferred to the main routine via common blocks.

## C.2.1 Routines that call read\_splups

Every routine that makes a call to read\_splups.pro has to be modified. Two changes are needed:

- 1. the call to read\_splups
- 2. the upsilon common block which contains the spline data

The read\_splups call used to be

```
read_splups,upsname,t_type,gfu,deu,c_ups,splups,upsref
```

The new call is

```
read_splups, filename, splstr, splref [, /prot]
```

where /prot should be set if proton rates are to be read. The original common block had the form

```
COMMON upsilon,t_type,deu,c_ups,splups
```

The new one should be

```
COMMON upsilon, splstr
```

## C.2.2 read\_splups

This reads data from .splups or .psplups files into an IDL structure (the previous version read data into several individual arrays). The call is

```
IDL> read_splups, filename, splstr, splref [, /prot]
```

The structure splstr has the following tags

```
.lvl1 lower level index
.lvl2 upper level index
.t_type transition type
.gf    gf value
.de    Delta-E for transition (rydbergs)
.c_ups    the scaling parameter
.nspl    number of spline points
.spl    Vector of length 9, containing spline points
```

## C.2.3 descale\_all.pro

This routine directly replaces descale\_ups.pro in the CHIANTI software. It is called as

An important difference is that the temperature is specified directly whereas previously the scaled temperature was given. In addition, several temperatures can be given at once rather than just one.

Note that there is no difference in how this routine treats the descaling of proton rates. The only place in the CHIANTI software where this routine is called is in pop\_solver.pro.

## C.2.4 pop\_solver.pro

The way electron excitation rates are included in pop\_solver has been changed. Only a single for loop is required now as the routine goes through each line in the structure. In addition, the routine can now descale the upsilons for several temperatures simultaneously.

## D The extra set of complementary routines

This section describes the features of the routines that are contained in the extra/ directory and that were contributed by Peter Young:

- dens\_plotter.pro A widget routine to allow the analysis of density sensitive ratios.
- temp\_plotter.pro A widget routine to allow the analysis of temperature sensitive ratios.
- g\_of\_t.pro To compute the G(T) of selected lines.
- pop\_plot.pro To plot  $n_i A_i i/N_e$  values as a function of  $N_e$
- show\_pops.pro To display populations of significant levels in a CHIANTI ion model
- emiss\_calc.pro To compute the emissivities of all lines of a specified ion over given ranges of temperature and density.
- integral\_calc.pro To compute the atomic data integral for use in column or volume emission measure work.

These routines, described in more detail in Sect. D.2 below, have slightly different units of outputs, compared to the other routines.

## D.1 Definitions

First of all, Sect. 8 gives the theory behind the interpretation of optically-thin emission lines which serves to set out the notation used here. Going back to Eq. 2, we write

$$N_{\rm i} = 0.83 F(T) Ab(X) N_{\rm e} n_{\rm i},$$
 (38)

where F(T) is the ionisation fraction (independent of  $N_{\rm e}$  in current ion balance calculations),  $Ab({\rm X})$  the abundance of the element relative to hydrogen, and the ratio of hydrogen to free electrons has been taken as 0.83, as hydrogen and helium are completely ionised for temperatures  $T > 10^4$  K.

The emissivity of the emission line resulting from a j-to-i radiative decay is defined as

$$\epsilon_{ij} = \Delta E \, N_i \, A_{ii} \tag{39}$$

and has units of erg cm<sup>-3</sup> s<sup>-1</sup>. Often the alternative notation  $\epsilon_{\lambda}$  will be used where  $\lambda$  is the wavelength of the emitted radiation in Angstroms (Å), and  $\lambda = 1.986 \times 10^{-8}/\Delta E$  for  $\Delta E$  in ergs. We will also define the *ion emissivity* as

$$\varepsilon_{ij} = \Delta E \, n_{j} \, A_{ji}. \tag{40}$$

In order to relate the emissivity to the actual observed intensity of a line, we make use of the third assumption, which tells us that the intensity is proportional to the emissivity of the plasma, and so

$$P_{\lambda} = \int \epsilon_{\lambda} \, \mathrm{d}V,\tag{41}$$

where  $P_{\lambda}$  is the power in an observed line (units: erg s<sup>-1</sup>), and dV is a volume of plasma with temperature T and density  $N_{\rm e}$ .

Expanding  $\epsilon_{\lambda}$  using Eqs 38 and 39 gives

$$P_{\lambda} = 0.83 \,\Delta E \,Ab(X) \int F(T) \,n_{\rm j} A_{\rm ji} N_{\rm e} \,\mathrm{d}V. \tag{42}$$

An important feature of emission measure studies is to isolate those lines for which  $n_{\rm j}A_{\rm ji} \sim N_{\rm e}$ . By analysing only such lines, we are essentially separating the determination of the emission measure from the determination of the plasma density. If the lines all had different density dependencies, then it would be necessary to determine the density variation with temperature before finding the emission measure. If the  $n_{\rm j}A_{\rm ji} \sim N_{\rm e}$  relation is assumed then we write

$$P_{\lambda} = \Delta E \, Ab(X) \int G_{\lambda}(T) \, N_{\rm e}^2 \, dV \tag{43}$$

where

$$G_{\lambda}(T) = 0.83 F(T) \frac{n_{\rm j} A_{\rm ji}}{N_{\rm e}}$$
 (44)

which is the so-called 'G-of-T' function.

On account of the ionisation fraction F(T) this function is sharply peaked, and a common approximation (e.g., Pottasch [3], Jordan & Wilson [1]) is to assume that G(T) has a constant value over a narrow temperature interval around  $G(T_{\text{max}})$ , where  $T_{\text{max}}$  is the temperature of

maximum ionisation for the ion. Here we will use the temperature of maximum emission or  $T_{\text{mem}}$  which is the temperature at which  $G_{\lambda}$  has its maximum. Defining

$$G_{\lambda,0}(T) = \begin{cases} C_{\lambda} & |\log T - \log T_{\text{mem}}| < 0.15\\ 0 & |\log T - \log T_{\text{mem}}| > 0.15 \end{cases}$$
(45)

we require that

$$\int G_{\lambda}(T)dT = \int G_{\lambda,0}(T)dT \tag{46}$$

SO

$$C_{\lambda} = \frac{\int G_{\lambda}(T)dT}{T_{\text{mem}}(10^{0.15} - 10^{-0.15})}.$$
(47)

Our expression for  $P_{\lambda}$  thus becomes

$$P_{\lambda} = \Delta E \, Ab(X) \, C_{\lambda} \, EM(V) \tag{48}$$

where

$$EM(V) = \sum_{i} \left( \int_{V_i} N_e^2 dV \right) \tag{49}$$

is the volume emission measure. Each volume  $V_i$  contains plasma with temperatures such that  $|\log T - \log T_{\text{mem}}| < 0.15$ , and the sum over i is required in case there are distinct regions along the line of sight that satisfy this condition on T.

Now, solar emission lines are often measured as intensity (or radiance), I, with units typically of erg cm<sup>-2</sup> sr<sup>-1</sup> s<sup>-1</sup>. This quantity is related to  $P_{\lambda}$  by

$$P_{\lambda} = 4\pi \int I dA \tag{50}$$

where dA is the projected area of the emitting element. One thus relates the observed intensity to an emission measure by

$$4\pi I = \Delta E \, Ab(X) \, C_{\lambda} \, EM(s) \tag{51}$$

where EM(s) is the column emission measure, where s is the line-of-sight depth of the emitting region.

Stellar emission lines are measured in flux (or irradiance), E, with units typically of erg cm<sup>-2</sup> s<sup>-1</sup>. E is related to  $P_{\lambda}$  by

$$P_{\lambda} = 4\pi d^2 E \tag{52}$$

where d is the distance to the object. The observed flux is then related to the emission measure by

$$E = \frac{1}{4\pi d^2} \Delta E \, Ab(X) \, C_{\lambda} \, EM(V). \tag{53}$$

If one treats the emitting region as a uniform, spherical shell of thickness h then  $dV = 4\pi R^2 dh$  (R the distance from the star centre of the shell; typically  $R = R_*$ , the radius of the star) and so the expression for E becomes

$$E = \frac{1}{2} \frac{R_*^2}{d^2} \Delta E Ab(X) C_{\lambda} EM(h). \tag{54}$$

where EM(h) is the emission measure over height. The factor 1/2 denotes that half the photons from the shell are emitted towards the stellar surface and so are destroyed. Jordan and co-workers (see, e.g., Jordan & Wilson [1], Jordan & Brown [2]) utilise this definition and an assumption of spherical symmetry to deduce energy balance relations in solar and stellar atmospheres.

## D.2 The primary routines

The routines are divided into *primary* and *secondary* routines. The secondary ones are called by some of the primary routines, and chances are that you won't have to use them too often. They are described in Sect. D.3.

All of the routines have headers which give more detailed information about how they work. This header can be read in the normal IDL way through, e.g., doc\_library, 'ratio\_plotter'.

### D.2.1 pop\_plot.pro

This routine plots the values of

$$10^{20} \,\Delta E \, n_{\rm i} A_{\rm ii} / N_{\rm e} \tag{55}$$

against  $N_{\rm e}$ . As discussed in Sect. 8, if we only study lines in the emission measure analysis for which this quantity is independent of density, then the derived emission measure is independent of the plasma density.

Example: For Fe XIII, select a line/blend from lines in the range 200 to 205 Å

Note how no single line shows zero density dependence, and so care should be taking in using Fe XIII in emission measure analyses. Compare with Fe XVI:

where both the 335 and 360 lines are OK.

#### D.2.2 integral\_calc.pro

This routine calculates  $C_{\lambda}$ , defined in Eq. 47. It displays both this value and the values of  $\Delta E \ C_{\lambda}$  and  $4\pi/\Delta E \ C_{\lambda}$ . For lines for which  $n_{\rm j}A_{\rm ji} \sim N_{\rm e}$ ,  $C_{\lambda}$  is insensitive to  $N_{\rm e}$ , but for other lines  $N_{\rm e}$  should be specified. Note that for blended lines only  $\sum \Delta E \ C_{\lambda}$  and  $4\pi/\sum \Delta E \ C_{\lambda}$  are output. The routine also outputs the  $T_{\rm mem}$  of the lines, accurate to 0.02 dex.

Example: Work out  $C_{\lambda}$  for the Fe XIII lines between 200 and 205 Å at a density of  $10^9$  cm<sup>-3</sup>.

From Eq. 51, an observed line intensity of 100 erg cm $^{-2}$ s $^{-1}$ sr $^{-1}$  for the 202.044 line implies a column emission measure of  $EM(s)=100\times 1.614\times 10^{20}/Ab(Fe)$ , where  $1.614\times 10^{20}$  is taken from 4pi/DE\*C\_lambda column of the output.

For Fe XIV, one can do:

integral\_calc, 26, 14, wrange=[210, 220], dens=9.

and so to get the same column emission measure for Fe XIV  $\lambda 211.32$ , an intensity of  $100 \times 1.614 \times 10^{20}/2.280 \times 10^{20} = 70.8$  erg cm<sup>-2</sup>s<sup>-1</sup>sr<sup>-1</sup> is required, where  $2.280 \times 10^{20}$  is the value of 4pi/DE\*C\_lambda for Fe XIV  $\lambda 211.32$ .

## D.2.3 temp\_plotter.pro and dens\_plotter.pro

Both temp\\_plotter.pro and dens\\_plotter.pro call a widget-based routine (ratio\_plotter, via the keywords /temp and /dens) that allows the thorough investigation of density or temperature sensitive ratios. Observed line intensities can be input for line ratios, and densities or temperatures derived.

Example: to study density sensitive ratios of Fe XIII, simply type in

Try inputting some line intensities and errors from the SERTS-89 spectrum (Thomas & Neupert [4]), and comparing the derived densities with those found by Young, Landi & Thomas [5] in Table 20.

#### D.2.4 show\_pops.pro

Gives percentage level populations for all levels within the specified ion that have populations greater than 0.01%.

Example: Compute level populations for Fe XIII at a density of  $10^{10}$  cm<sup>-3</sup>:

$$show_pops, 26, 13, dens=10$$

#### D.2.5 g\_of\_t.pro

Eq. 44 gives the definition of the *contribution* function as calculated by the g\_of\_t routine. In it's default setting g\_of\_t.pro actually calculates:

$$\Delta E \ G_{\lambda}(T) = 0.83 \, \Delta E \ F(T) \, \frac{n_{\rm j} A_{\rm ji}}{N_{\rm e}}$$

which is more useful when considering blends of lines at different wavelengths. The  $\Delta E$  can be 'disabled' with the /no\_de keyword. It is also useful to multiply the above function by the element abundance, and this is accomplished with the /abund keyword. The output function is tabulated over  $4.0 \leq \log T \leq 8.0$  at 0.1 dex intervals. For smaller intervals, see the ion\_interp routine.

Examples:

```
result=g_of_t(26,13,dens=9.)
result=g_of_t(26,13,wrange=[200,205],/abund)
result=g_of_t(26,13,/no_de)
```

One can also use this routine to derive the  $T_{\text{mem}}$  of the emission line, by way of the ion\_interp.pro routine, e.g.,

```
result=g_of_t(26,13,dens=9.)
ion_interp,t,result,ti,g_ti,10
print,ti(where(g_ti eq max(g_ti)))
```

result is tabulated at 0.1 dex intervals in temperature. ion\_interp interpolates result and in this case gives it at 0.01 dex intervals.

## D.3 The secondary routines

These routines are called by the routines above.

## D.3.1 emiss\_calc.pro

Calculates the ion emissivity (Eq. 40) for all transitions within the CHIANTI model of the ion. The returned data is in the form of a structure. The default is to calculate emissivities for temperatures  $T_{\rm max}$  and log  $T_{\rm max} \pm 0.15$ , and densities log  $N_{\rm e} = 8.0, 8.5, 9.0, ...., 12.0$ .

Example:

```
emiss=emiss_calc(26,13)
```

#### D.3.2 emiss\_select.pro

Allows the selection of lines/blends from the emiss structure created by emiss\_calc.pro. This routine is useful if you want to access the emissivities of lines directly, e.g.,

```
emiss=emiss_calc(26,13)
em202=emiss_select(emiss,wra=[200,205],sel_ind=sel_ind)
```

In this example, calling emiss\_select yields a widget that allows one to select a line/blend from the 200–205 Å range. The emissivities of this line blend will be contained in em202, while the emiss index/indices of this line/blend will be contained in sel\_ind.

#### D.3.3 ion\_interp.pro

When reading the ionisation equilibrium files, you will receive an array with absolute (as opposed to log) ion fractions tabulated at 0.1 dex intervals from log T=4.0 to 8.0. A common need is to interpolate this data and obtain the ion fraction tabulated at smaller intervals. As the ion fractions are generally sharply peaked, normal interpolation will lead to negative ion fractions at several temperatures, and so a more satisfactory method is to

interpolate the log of the ion fraction. However, you need to take the log of only the non-zero values of the ion fraction.

The several lines of code required to perform the interpolation are straightforward but irritating (when typed on many occasions!), and so this routine performs the task.

Example: Use g\_of\_t to create a G(T) function for one of the Fe XIII lines,

```
result=g_of_t(26,13,dens=9.)
ion_interp,t,result,ti,g_ti,5
```

The G(T) function is now tabulated at 0.02 dex intervals. Note that if t is not specified, it is assumed to be a vector going from 4.0 to 8.0 in 0.1 dex intervals.

## E More details

More details are found in the program headers (see the html version of this guide).

### E.1 The CHIANTI line intensities structure

The tags of the line intensities structure are:

- .lines A structure containing information about the lines.

  Its size is the number of lines in the spectrum. The tags are:

  .iz The atomic number of the elements (e.g., 26=Fe)

  .ion The ionisation stage (e.g., 13=XIII)

  .snote The identification of the ion (e.g., 'Fe XXIV d')
  - .ident The identification of the transition, configuration and terms in text form.

  - .lvl1 The lower level of the transition (see .elvlc file for ion)
  - .1v12 The upper level for transition.

.tmax The temperature of maximum emission of the line.

If the G(T) are output, tmax is the maximum of G(T).

If the isothermal approximation is used tmax=0.

If a DEM is used, tmax is the maximum of the emissivity that includes the product of the ion fraction and the DEM.
Rounded to nearest 0.1

.wvl Wavelength of the transition, in Angstroms.

.flag A flag, =-1 if the line has only theoretical energy levels. Otherwise flag=0.

.goft The G(T) of the line (optional /exclusive with .int).

.ioneq\_name The ion balance file used (full path).

.ioneq\_ref The references.

.dem\_name The differential emission measure file eventually used (full path).

.dem The Log10 DEM values

.dem\_ref The references.

.model\_name A string indicating the model used:

1- Constant density

2- Constant pressure

3- Function (Te,Ne)

.model\_file Full path of the (Te,Ne) file if defined. Null string otherwise.

.model\_ne the Ne value(s).

- a scalar if 'Constant density' is selected.
- an array if 'Function' is selected.
- 0. if constant pressure is selected.

.model\_pe the Pe value.

- a scalar if constant pressure is selected.
- 0. if 'Constant density' is selected.
- an array=density\*temperature if 'Function' is selected.

.model\_te the Te values if 'Function' is selected. Otherwise 0.

.wvl\_units The wavelength units.

.wvl\_limits The wavelength limits specified by the user.

.int\_units The intensity units (erg/cm2/s/sr or phot/cm2/s/sr) if
 intensities are calculated, otherwise the G(T) units
 (erg cm3/s/sr or phot cm3 /s/sr)

#### .logt\_isothermal

The Log10(T) values used.

#### .logem\_isothermal

The Log10(EM) values used.

- .date The date and time when the structure was created.
- .version The version number of the CHIANTI database used.

#### .add\_protons

A flag (0/1) to indicate whether proton data were used (1) or not (0) to calculate the level population.

#### .photoexcitation

A flag (0/1) to indicate if photoexcitation was included (1) or not (0).

## .radtemp

The blackbody radiation field temperature used (if photoexcitation was included).

#### .rphot

Distance from the centre of the star in stellar radius units (if photoexcitation was included).

## E.2 The CHIANTI spectrum structure

The spectrum structure output of MAKE\_CHIANTI\_SPEC has the following ADDITIONAL tags (compared to the tags of the CHIANTI line intensities structure created by CH\_SYNTHETIC:

LAMBDA The array of X-values SPECTRUM The array of Y-values

UNITS The units of LAMBDA, SPECTRUM

WRANGE The wavelength range INSTR\_FWHM The Instrumental FWHM

BIN\_SIZE Width of the Bins (fixed) in angstroms

ABUND\_NAME The CHIANTI abundance file name

ABUND The abundance values

MIN\_ABUND The minimum abundance value used

ABUND\_REF The references

CONTINUUM The values of the continuum (if calculated)
FILE\_EFFAREA The Effective Area File used (optional)
EFFAREA The array of effective area values

(optional - same size of LAMBDA)

.LINES An array of structures, for all the lines used

to calculate the SPECTRUM.

The tags are the same as those created by

CH\_SYNTHETIC, plus

.PEAK The peak intensity of the line in the spectrum

(approx. value)

# F List of main CHIANTI routines with description and headers

Only available in the html version.

# G List of all CHIANTI routines with description and headers (alphabetical order)

Only available in the html version.
